Abstract:

The title of our contribution refers to Alexander Kluge's movie, “Der Angriff der Gegenwart auf die übrige Zeit” (“the assault of the present on the rest of time”). The question we ask is how financialized capitalism shapes and formats the politics of the future. Our central tenet is that, far from providing an engine 'imagining' futures that substantively guide (collective) actions, finance 'consumes' forecasts, plans, or visions in its present coordination process. While the “oscillation” between present futures and future presents has been identified as a defining feature of modern conceptions of contingency, freedom, and choice (Luhmann; Esposito), these two temporal modalities are collapsed in contemporary financial markets in an ongoing 'pricing in' of various possible future states. Projected futures do not substantively shape collective paths towards them or instruct social learning, but are calculatively assimilated to improve coordination between present prices. Fatally, central banks have been at the forefront of “synchronist” (Langenohl) finance, believing that as long as numeric calibration of their own and the markets' expectations as expressed in prices align, they have rendered capitalism governable. Under this regime, central banks really do *not* govern inflation, but inflation expectations as expressed in the “yield curve” and built into interest rate derivatives. We argue that financial techniques built on the efficient market hypothesis and the Black-Scholes-Merton formula, as two theoretical articulations of this modern “synchronist” (Langenohl) temporality of finance, allow central banks to ignore possible “random” fluctuations in actual inflation and concentrate on the internal calibration of present futures as the sole criterion for monetary policy success. We show that the resultant “assault” on “future presents” was an important factor in the run-up to the crisis of 2007-9. Central banks deliberately attempted to eliminate uncertainties in markets about the future course of monetary policies. For that purpose, shared fictions about the underlying logics of Western economies (real interest rates, NAIRU etc.) were rigidly built into the structures of asset prices. Moreover, since central banks and market actors aligned their expectations over real interest rates, market actors could act as if their uncertainties about future liquidity needs could be neglected, since current money market and official lending rates were supposed to already define the price of liquidity tomorrow. In the last part of the contribution, we will extend this argument to contemporary quantitative easing, to show how it reinforces the pitfalls of generating expectations of economic prosperity and stability via the contemporary financial system.

Introduction

In Alexander Kluge's movie, "*Der Angriff der Gegenwart auf die übrige Zeit*" ("the assault of the present on the rest of time"), people live in a "distended present" (Kluge, Evans, and Liebman 1990, *passim*): faced with uncertain (personal and societal) futures, they are unable to make lasting decisions and remain trapped in an unending present. In this contribution, we discuss another "assault on the rest of time" that was just in the making when Kluge's film appeared in 1985 – namely, the ways in which finance shapes and formats the politics of the future. Our central tenet is that, far from providing an engine for imagining substantive futures that guide (collective) actions, finance "consumes" forecasts, plans, or visions. They serve as mere signals (Langenohl and Wetzel 2011) fueling an increasingly short-term (Montagne 2009), febrile hunt for novelties from which profit can be generated by beating others to it.

In (economic) theory, prices will oscillate (more or less) evenly around its expected 'intrinsic' value in response to incoming signals, so that "the time average of an observable [is] equal to its expectation value" (Peters 2019, 1216). Based on this statistical premise of "ergodicity", there can be no fundamental discontinuity between future, on the one hand, and past and present, on the other – so that *rational* intertemporal calculation and expectations become possible. (Beckert and Bronk 2018: 18-20).¹ As the formal models and calculative devices through which economic agents project and imagine the future are built from these assumptions, the ergodic continuity between past, present and future effectively becomes part of the background frame in terms of which signals *about the future* are given meaning and translated *in the present*. We thus suggest that the temporality of contemporary finance is at odds with modernist conceptions of futurity as involving an epistemic "back and forth" between a given present and an open future, out of which emerge contingency, freedom and choice (Luhmann 1976; Esposito 2004). The 'future' toward which finance is oriented (Arrow 1978) is constantly collapsed into the present through an ongoing process of 'pricing in' the future and rendering it calculable according to an a-temporal space of possibilities. For modern finance, the future has become a useful means for acting *in the present*, rather than an ontologically distinct state which we imagine and construct based on joint imaginations as we proceed towards it *from the present*. We develop this point by discussing the case of derivatives markets. We show how derivatives markets depend directly on the assumption of a "synchronicity" of present and future, built directly into the central valuation device on which the functioning of these markets depends – the so-called *Black-Scholes-Merton* formula. We extend this

1

In technical terms, "[e]rgodicity is fulfilled, if the time average of a system or process equals its ensemble average. The time average is the average of one observed trajectory or realisation of a process (one time series). The ensemble average is the average over every possible state of a system." (Kirstein 2015: 1). The assumption of ergodicity is crucial for predominant formalizations of economic dynamics as "the ergodic case is much easier to handle mathematically", although in principle "non-ergodicity is a necessary property of a mathematical model, if the model is supposed to describe trajectory occurrences of endogenous novelties and change" (*ibid.*).

argument in the second part of our contribution, where we describe how central banks have developed a finance-oriented and finance-based “governmentality” (Foucault 2007[1978]). Under this regime, central banks really do *not* govern future inflation, but present *expectations* of future inflation as expressed in the “yield curve” and built into interest rate derivatives. We suggest that the use of Rational Expectations models that construe the future as ‘conserved’ within an ergodic, a-temporal world allows central banks to ignore possible ‘random’ fluctuations in *actual* inflation and concentrate on the internal calibration of present expectations of future inflation as the sole criterion for monetary policy success. We show that this “assault” of present expectations on a future that never becomes actualized was an important factor in the run-up to the crisis of 2007-9. Central banks have facilitated forms of financial valuation that rely on key fictions of an ergodic world (in particular the “natural” interest rate), by stabilizing the expectational parameters which manifest these fictions, and have thus helped to black-box uncertainties. The crisis itself, and post-crisis interventions, have not led to a “reckoning” with a different temporality, but activated various support mechanisms and new policy tools (e.g. “forward guidance”) that shield and maintain this ‘practical fiction’ and “infrastructure” (Star and Ruhleder 1996) of an ergodic world for contemporary finance. What has become clearer, though, is that the particular constellations between policy institutions and financial markets found in contemporary capitalism do not support economic prosperity and sustainability for society as a whole.

The ergodic world of “quantitative” finance

Compared to the embedded, “boring finance” of the 1950s to the 1980s, in the contemporary financial system, the contingency of all financial activity on the future has become much more visible. In particular, the “openness of the future” (Beckert 2015: 35ff. and the problem that an open future is necessarily contingent and therefore “fundamentally uncertain” (Knight 1921) has moved centre-stage in discussions about contemporary finance. Whereas in the “golden age of capitalism” (Marglin and Schor 2000), finance lived well by the “3-6-3” rule (charging a three percent mark-up on credit over the three percent interest paid out on deposits, and be off to the golf course at 3 p.m.) (Walter 2006), the de-regulation and financial innovation that started in the 1970s (Helleiner 1994) has turned the future into an explicit epistemic problem. As a result, financial (and economic) activity has become much more directly dependent on the elaboration of “imagined futures” and calculative “instruments of imagination” for the coordination of expectations (Beckert 2016: 216ff.). Since the liquidity and stability of markets hinges directly on the continuity of valuations (and the knowledge underpinning them) (Carruthers and Stinchcombe 1999), this means that these epistemic practices and calculative instruments, and the joint expectations of the futures that they help construct, have become central to the functioning of contemporary finance.

It has therefore become common for both practitioners and observers to understand contemporary finance as revolving around the problem of mitigating the fundamental epistemic uncertainty of a future that is open and contingent. In this view, finance has become a primary site for *Acting in an Uncertain World* (Callon, Lascoumes, and Barthe 2009), where market participants learn to forecast and imagine such futures through calculative devices and/or hedge against uncertainties using various financial tools. Finance thus seems to derive its societal role and significance as *the* institution of modernity to cope, manage and live with an uncertain future and to render this open future as a space of possibilities – for speculation, investment, hedging, insurance, betting etc.

There is, however, some reason to be cautious about the notion that uncertainty in finance is (primarily) a function of the irreducible gap between *present futures* and actual *future presents*. The historian Reinhart Koselleck (1989) has theorized this gap as a result of historical experiences that have led actors to distinguish these two distinct forms of “future”: the future as imagined in the present (‘present future’), and future presents, i.e. future states of the world when they (have) become present, or actualized. However, this decidedly modern form of temporality is not the one that reigns in contemporary finance.

To argue this point, we need to look at precisely how epistemic accuracy of expectations about the future-present matters in finance. As John Maynard Keynes and Hyman Minsky have pointed out long ago, the openness of the future manifests itself as an ‘economic survival constraint’: False or inaccurate present-futures are costly, or even life-threatening to economic units, if investments fail. For that reason, Keynes and Minsky thought that as uncertainty becomes more directly and intensively felt, economic units avoid tying down their wealth in risky investments and protect themselves against adverse risks by stocking up on liquid reserves.

The key characteristic of this uncertainty – the uncertainty of having enough liquid means to meet upcoming obligations – is that it cannot readily be made measurable: It depends on the behavior of various other actors (e.g. money market lenders) and the various feedback processes by which one’s own and others’ decisions (e.g. asset sales) affect the state of the financial system as a whole. However, as central banks have encouraged and supported financial markets’ reliance on ‘ergodic fictions’ for valuation and risk management, this uncertainty has ceased to feature in the regular calculations and strategies of financial actors and in the structures of the financial system, giving way to a world in which actors act most of the times as if market liquidity and stable asset prices will be indefinitely maintained. To understand how and why, we need to understand the role played by Rational Expectations (as both a category of practice and a theory) in contemporary finance. Discounting expected future returns to calculate an asset’s present value requires knowledge of the future development of macroeconomic variables (such as growth, interest rates or inflation, etc.) which, in models and formulas derived from Rational Expectations Economics, shape this present

value, as joint expectations about such parameters become widely embedded in valuations (Bryan and Rafferty 2006). Such parameters come to define a “normality” as background to and condition of asset valuations, with market actors closely tracking any anomalies that might affect asset values (Zaloom 2009; Christophers 2017). This ‘normality’ has become an intrinsic background for the joint structures of knowledge that secure the continuity of valuations and market transactions, and thus undergird the liquidity and stability of “market-based finance” (Hardie and Howarth 2013). This background establishes a (calculative and epistemic) continuity between the present and the future, built directly into the fabric of financial markets, against which more narrow present-futures can be elaborated, processed, adopted or discarded. The intense concern with the future in contemporary finance is thus made possible by this “synchronist” (Langenohl 2018) background, which anchors the impressive array of instruments of imagination in an a-temporal skeletal structure on which the validity of any calculation of present futures depends.

This ergodic conception of time (Kirstein 2015) derives its importance for contemporary finance particularly in those contexts in which the respective parameters are directly incorporated into the markets’ valuation devices. A case in point are the derivatives markets, which do not value and trade normal financial assets (such as stocks or currencies), but which are based on contracts through which parties directly wager on future prices of underlying assets in relation to specific future events. Derivatives wager on (clearly circumscribed) imagined futures and the valuations they imply (through discounting), without the need to possess or actually trade underlying assets. This might suggest that, if anywhere, it is in the derivatives markets that actors care for whether their present futures actually become future presents at some point in time. But this is not how valuation and pricing works in these markets, which are based on the common valuation infrastructure that relies on the Black-Scholes-Merton formula (Watson 2007; MacKenzie and Millo 2003; Black and Scholes 1973). With this formula, traders no longer focus on particular events and future-presents as they arrive, but instead trade what is called “volatility” – a measure of the variability of prices over time that is dependent on such variation remaining ergodic (Davidson 1982). Using this calculative tool, participants thus engage in a market process in which particular events and risks are subsumed with regards to a ‘synchronic’ background system of valuation and pricing.

The Black-Scholes formula thus premises its validity and applicability on this assumption of a fundamentally static and continuous world that does not undergo any fundamental substantive changes. In this world, present-futures are nothing but short-lived inputs or signals that generate possibilities for arbitrage but do *not* affect the static background continuity that undergirds the system. However, in the case of “Black Swan” events (Taleb 2007), that is when highly improbable “tail-end” events in a probability distribution occur, a system of valuations premised on ergodicity becomes incoherent, leading markets to freeze. As Donald MacKenzie (2004; MacKenzie and Millo

2003) has shown, the 1987 stock market crash drove home the limits of this ergodic depiction of temporality, and practitioners adjusted their Black-Scholes pricing *ad hoc* and modified the price curve for options so that longer-termed options now include an uncertainty premium (the so-called “volatility smile” or “skew”) on top of their ‘ergodic’ price.

Derivative markets thus highlight particularly clearly how the synchronist background against which financial valuation operates mitigates uncertainty, not by encouraging actors to reckon with an uncertain future, but by excluding the possibility that the future might be discontinuous with the present (in aggregate terms), in any radical sense. For the continuous functioning of financial markets, it is more important to uphold a stable background of expectations than to know the future accurately. The synchronist frame operatively decouples actions taken in reaction to and in terms of present-futures from the actual future-present(s) that come to pass.

Many observers and practitioners have noted how this separation from this calculative background has made the sequential processing of transitory present-futures at the ‘surface’ of the market almost ritualistic (e.g. LiPuma 2017; Ayache 2016). The unfolding of present-futures is largely irrelevant to and does not feed into the static expectations about the future encoded in the background, which is re-asserted or “performed” anew with every transaction that makes use of instruments of valuation or calculation derived from Rational Expectations models (cf. LiPuma 2017). Derivatives markets thus form the extreme end of a continuum, but highlight the logical conditions of why the liquidity and stability of modern financial markets depends on this calculative background. They illustrate why the *accuracy* of expectations is not actually put to the test (or least only idiosyncratically, for individual traders) as long as markets can *operatively* hold onto this “useful” fiction of a continuous, normal and ergodic world. As a result, for modern finance, the future itself is continuously absent (Law and Urry 2004): it is a horizon of possibilities that provides inputs for arbitrage, but must remain invisible at the level of the constitutive fiction of the never-changing future on which market stability rests.

The modern financial system is thus based on ‘willful’ or “strategic ignorance” (McGoey 2012) of the future present as a constitutive principle: excluding the possibility of substantive discontinuities between present and future is what prevents uncertainty and secures the possibility of action in markets in the present. As market coordination increasingly depends on the construction, projection and diffusion of present-futures, this common background has gained in importance. It allows translating present-futures into numeric prices, and thus is central to securing the congruence of expectations (about present and future prices) in markets. The financial system’s ability to process information about the future thus depends on the continuous operative denial of the openness of this very future. Whatever individual actors might think privately, at the level of the market-public, uncertainty must not be allowed to manifest itself, but must continuously be absorbed and

neutralized – as a precondition for the system’s ability to process any signals about the future that might entail (limited) re-valuations and price changes at all.

Evidently, excluding the possibility of a fundamental discontinuity of the economic present and future mathematically does not protect financial actors from suffering the consequences of being (collectively) wrong. However, Minsky has shown with his now famous “financial instability hypothesis” (Minsky 1980), if central banks are actively working to protect markets from a breakdown of the fictional continuity and the ‘normal market conditions’ it enables, they are effectively removing the survival constraint on financial institutions. In other words, they protect them from ever having to face fundamental discontinuity, allowing them instead to continue processing present-futures without concerning themselves with their accuracy. As he pointed out, by continuously neutralizing the effects of fundamental dissonances about the future, and shoring up ‘normal’ assumptions about the future in order to secure the ‘normal’ operations of the system, one also abolishes any incentives to look out for, and be prepared for, the possibility of fundamentally different futures, blanking out underlying systemic uncertainties.

The more market actors are assured that normal market conditions will continue (indefinitely) into the future, the more the future becomes a “useful fiction”, that is continuously presupposed but never actually must affect the normal operations of the system. As we shall see in the next section, central banks’ efforts to gain “infrastructural power” (Walter and Wansleben 2019; Braun and Gabor 2019; Braun 2018a), by seeking to develop technologies for influencing financial markets (and the economy) by “governing through expectations” (Wansleben 2018; Braun 2015), have become directly complicit with this specific temporality of modern finance.

Hegemonic futures in financialized capitalism

The role of an ergodic world as a calculative background for market coordination has gained general societal and economic importance through processes of financialization. Financialization can be used as a descriptive term, to depict how the size of finance has grown compared to the rest of the economy (Stockhammer 2008); how corporations shift their sources of profit from production to financial activities (Krippner 2005); and/or to capture how households in Western economies have become increasingly entangled in financial markets, as mortgage holders, employees with private pension plans, owners of life insurance products and the like (van der Zwan 2014; Davies 2009). We use the concept here in a related, but somewhat different sense. Our interest is in how the logics of coordination reliant on particular conceptions of futurity become dominant for the ways in which capitalist democracies are rendered governable. We are thus interested in reconstructing a particular “governmentality” that is not exhaustively described with regards to shareholder value, speculative identities or even particularistic elite interests, but concerns the fundamental ways in

which capitalism is thought to be governable and controllable *tout court*. This sounds like a rather grand claim. But we believe there is strong evidence for the rise of finance as a new governmentality that is closely associated with the emergence of central banks as the most powerful governors in contemporary capitalist regimes.

The proposition that we make therefore is that central banks have contributed to transcending the role of contemporary finance by tying their own practices of macroeconomic policy making to this particular realm (Krippner 2011). We will here limit this discussion to the symbolic-communicative dimension of central banks' governing practices - a topic that has raised much interest in sociological (Braun 2015) and anthropological research (Holmes 2013). The innovation identified by these scholars is that central bankers have learnt to govern monetary developments by communicating how they plan to intervene in order to "govern" the future (from the present); the markets, reacting to such signals then adapt accordingly, performatively bringing about the effects that the central banks hope to obtain. The point that we want to elaborate on here is that such "performative" central banking is not a neutral strategy to achieve legitimate political objectives like low inflation and stable growth. These practices of governing rather require that central banks align their interventions with the structure of financial markets and with the particular mechanisms that rely upon and re-inscribe ergodicity within them.

This firstly entails a subtle, but important, shift in the very object of governing. The sociological argument underlying the idea of "expectational governance" is that central banks can control price-setting in the economy by influencing the expectations that economic actors have over changes in the inflation rate (Beckert 2016). When these actors – like wage bargainers - expect inflation to remain stable, they will be more moderate with their wage claims and their mark-up pricing and thereby *produce* the low inflation rates that they assume to prevail. This self-confirmatory logic is intuitive. But surveys have shown time and again that the general public's expectations are relatively fickle and that inflation rates can be influenced by various factors, not all of which are expectational (Lombardelli and Saleheen 2003). Central bankers have resolved these uncertainties and problems with their governing by redefining what they actually control: *Not inflation itself, but inflation expectations as incorporated into financial markets' calculations and operations*. The assumption is that, as long as these remain stable, it does not matter that prices actually fluctuate somewhat or that most people do not have a good understanding of how inflation will evolve. As a consequence, cognitive and normative expectations inherent in markets, rather than the demands, claims, and ideas from broader society, become the linchpin for assessing central bankers' success and for orienting their macroeconomic policies. Financial market expectations thus have become central banks' primary objects of governing; all that matters is that financial market prices – primarily long-term interest rates – reflect expectations that inflation will remain stable and low.

This re-orientation to markets was well articulated by Ben Bernanke, an architect of inflation targeting, who claimed that “monetary policy is a cooperative game. *The whole point is to get financial markets on our side* and for them to do some of our work for us” (cited in Mallaby 2017: 612, our emphasis). In other words, central banks rely on financial markets to assume a hegemonic role in defining economic futures more generally, and they reinforce this hegemony by aligning their communications with the specific logics of these markets.

This brings us to a second dimension of such finance-oriented expectation coordination – the fictitious elimination of radical uncertainty and the simulation of an ergodic socio-economic system with stable parameters within which financial expansion can unfold. To illustrate this point, let us imagine a central bank that has some expertise on finance and the economy, but only imprecisely and ‘with uncertainty’ knows how the economy will evolve going forward – what the level of employment will be, how much output is going to be produced, how such employment level and output are going to relate to the productive capacities of an economy, how such interactions will affect the price level – not to speak of the uncertainties arising from developments in asset and credit markets that affect banking, household wealth, productive facilities, consumer spending etc. With the introduction of inflation targeting since the late 1980s, it became imperative to eliminate these uncertainties and impose a rigid framework in which the respective developments are articulated in precise terms (Walter and Wansleben 2019). In essence, this new framework rests on ‘new neo-classical’ Keynesian models (Goodfriend 2002) that construe an economy that tends towards general equilibrium – a state at which levels of employment are just enough to use the economy’s full capacity without causing excessive inflation and at which the “natural” interest rate prevails, which equilibrates demand and supply for capital (Woodford 2009). Based on this conception, central banks and markets then coordinate their expectations about how the central banks ought to bring the nominal short-term interests in line with these imagined equilibrium properties of the system – with some allowance for short-term interventionism as a result of “nominal rigidities” (e.g. due to fixed contracts). Such coordination becomes institutionalized through ritual decision procedures and communications that confirm assumptions about present-futures that are being incorporated in market rates. Accordingly, what inflation architects saw a key feature and advantage of inflation targeting was that it created ever “fewer occasions on which the authorities’ behaviour - as opposed to the underlying economic developments - causes uncertainty in the markets” (Butler and Clews 1997: 48).

In other words, the tools and techniques of macroeconomic policy championed by central banks have enhanced and strengthened the ‘normality expectations’ undergirding valuations in financial markets. This has then reinforced the expansionary dynamics of finance, leading to a proliferation of contracts (e.g. of securitized assets), market relations and balance sheets that presuppose an unchanging macroeconomic background structure upon which financialization rests (Nesvetailova

2015; Mehrling 2011). Particular features of financialization, such as the interrelated expansion of asset and money markets, rely on these normality expectations and more generally on the notion that central banks will maintain stability in all major macroeconomic variables (inflation, interest rates) relevant for financial markets. As the transatlantic financial crisis of 2007-9 has brought home, the “success” of central banks to coordinate with finance should *not* be confused with the development of reliable ways to govern capitalist democracies. Indeed, the events in these years rather demonstrated that the self-validation between policy makers and market actors had become dissociated from the actual socio-economic structures – precarious labour market situations, debt pyramids etc. – to which their macroeconomic models and valuation practices purported to refer (e.g. Fligstein, Stuart Brundage, and Schultz 2017). However, this has not led to a fundamental questioning of the governmentality regime associated with financialization. Rather, central banks’ “unconventional” expansionary monetary policies since 2009 reflect a reinforcement of a finance-oriented and finance-centred policy making (Braun 2018b). Their central aim is to reinstall confidence within finance about the indefinite continuity of “normal” patterns of output, inflation, interest rates etc., with the intended effect of inducing market actors to re-engage in investments and credit provision that are believed to generate growth. Finance thus remains at the centre of macroeconomic governance and thus maintains its privileged role in “mature” capitalism.

To be fair, there has been some critical discussion amongst expert economists about the adverse consequences of such regimes. For instance, Tobias Adrian and Nelly Liang write that:

Monetary policy works through financial conditions on expected economic outcomes, but risks to financial stability involve potential tail risks. The tail risks to future macroeconomic outcomes manifest only in some states of the world, when adverse shocks are realized. These dimensions are important because they greatly complicate efforts to incorporate financial stability in the determination of monetary policy. Policy makers would need to look beyond expected conditions for downside risks that arise with uncertain probability in the future (2016: 4).

Yet there seem to be little appetite amongst policy makers to take seriously these adverse financial stability effects, not to speak of the broader societal problems, that arise from the current finance-oriented governance regime.

Conclusion

Up until now, the highly problematic “politics of the future” entailed by the characteristic temporality of modern finance, and its widening implications due to financialization, have by-and-large passed under the radar (but see Adkins 2018; Langenohl 2007; 2018). While our focus in this

essay has been on the role of technological and epistemic infrastructures in lending this temporality durability and a degree of invisibility, the concerns we would like to raise are related to these (for the most part, sociological and anthropological) “diagnostics of the present”.

To be sure, the fragilities in the financial system that result from the continuous need to stabilize the ‘discounted’ fictive future values in the present have been widely noted (e.g. Mehrling 2011; Nesvetailova 2007), but only rarely linked to the peculiar temporalities of modern finance (but see LiPuma 2017). More commonly, financial fragility is instead interpreted as an issue of *complexity* – to be addressed by increasing the transparency of markets, and in particular by reducing the epistemic uncertainty that this complexity generates with regard to the system’s own future (e.g. Gräbner and Kapeller 2015; Cooper 2011).

Following from our argument, the present attempts, through regulation and monetary policy, to manage and contain the complexity of contemporary finance may, paradoxically, contribute to instability if the main aim remains to stabilize the working fiction of an ergodic, ‘timeless’ temporality on which financial markets are premised. This ergodic normality has become the very foundation of the calculability of financial values (Peters 2019), its commensurability across assets and markets and thus the liquidity and stability of those markets themselves. This is all the more the case as there has been a marked, global trend towards market-based finance (Murau 2017; Gabor 2016) in which the ability to shift assets in markets has become the basis of liquidity (Mehrling 2011), increasing the systemic risk entailed by disruptions to this frame of calculability. The need to protect this temporality, the frame of calculability and structure of valuations it undergirds, forces central banks into continuing their role of reinsurer of systemic risk and market-maker of last resort that had already contributed to the 2007-2009 crisis, backstopping the value of a widening pool of (only seemingly) ‘liquid’ assets (Mehrling 2011; Borio and White 2004). The “unconventional” monetary policies of quantitative easing pursued by central banks around the world since 2008 even carry the rationality of restoring and safeguarding the technical presuppositions of ‘normal’ forms of governability in their name. Likewise, the “macro-prudential” financial regulation that has come to dominate regulatory debates (Coombs 2017; Baker 2013) attempts to correct the fragilities created by the ‘distended present’ of modern finance by increasing the transparency of risks (e.g. through stress tests), raising buffers and facilitating ‘efficient’ risk sharing within the financial system. Despite some undeniable innovations at the levels of technical frameworks and instruments at its disposal since 2008-09, monetary policy thus continues to be geared towards ergodicity as its operative framework. ‘Macro-pru’ and unconventional policies aim, first and foremost, at restoring and protecting *normal conditions* in financial markets, as a platform for effective monetary policy. This *normality* is conceived of in ergodic terms and observed through (mathematical) models premised on ergodicity. Deviations from normality thus become an impediment to be neutralized in

order to secure the inter-temporal consistency and effectiveness of monetary policy – rather than as (potentially) indicative of (fundamental) uncertainties of which market actors (and central banks!) would need to take heed and which might require adjustments to their calculative strategies. Instead, central banks proactively seek to restore ‘quasi-ergodic’ conditions in financial markets, by reducing what they perceive as market imperfections that prevent the even inter-temporal dissemination of monetary policy signals. However, in combating manifestations of uncertainty as *anomalies* that stand in the way of monetary policy operations premised on the ergodicity of finance and the economy, central banks are sterilizing the very signs that the future may indeed substantively differ from past and present. Their interventions provide financial markets with a working fiction of an ergodic world, and, rather than *removing* vulnerabilities, they counteract the very processes through which collective sense-making could solidify into effectively constraining price signals – until, that is, the next crisis...
