Understanding and Reducing Biases in Elite Beliefs About the Electorate

Miguel M. Pereira*
University of Southern California

Abstract

To be responsive, politicians have to rely on beliefs about public will. Previous research suggests that perceptions of public opinion are often distorted. However, it remains unclear (1) why reelection-seeking officials misperceive constituency preferences, and (2) how to mitigate these distorted beliefs. I argue that misperceptions result from unequal exposure to different subconstituencies, and a tendency of legislators to project their own preferences on voters. I find support for these arguments in a six-wave panel of Swedish MPs combined with mass surveys. Elite beliefs disproportionately reflect the preferences of more privileged voters and the personal positions of legislators. Additionally, an experiment with Swiss representatives leveraging real political events reveals how misperceptions can be reduced by encouraging a more balanced exposure to voters. The study concludes that economic and political inequalities are rooted in elite beliefs about the electorate and reveals ways to bolster the links between voters and their representatives.

How do politicians learn about public preferences? Office-seeking officials have incentives to be informed (Downs 1957; Geer 1996; Pereira 2020). However, a growing literature suggests that learning about what voters want is more demanding than originally suggested (Butler and Nickerson 2011; Druckman and Jacobs 2015; Sheffer et al. 2018). Representatives often have a distorted image of their constituents (Broockman and Skovron 2018; Converse and Pierce 1986; Erikson et al. 1975; Holmberg 1989; Kertzer et al. 2020; Miller and Stokes 1963). Hence, a key ingredient for policy responsiveness is frequently missing. This leads to two crucial questions that I explore in this article: (1) why do politicians misperceive public preferences; and (2) how can misperceptions be mitigated.

I explore two factors that may lead political elites to misperceive constituency preferences: inequalities in exposure and personal biases of legislators. First, representatives do not interact with all subconstituencies in the same way. More affluent and organized groups are more likely to make their voices heard in the policymaking process (e.g., Gallego 2007; Schlozman et al. 2012).¹ This “differential exposure” to more privileged subconstituencies can lead officials to rely disproportionately on these voices when forming opinions about public preferences. In short, inequalities in political resources across voters can generate distorted images of the constituency. Furthermore, legislators’ own personal background can also influence exposure. Policymakers are drawn disproportionately from more affluent segments of the electorate (Carnes and Lupu 2015), and the social networks of public officials can shape their image of the constituency (Campbell 2013). Taken together, these arguments suggest that misperceptions can result from the type of information that is more accessible to politicians.

However, unequal exposure only tells part of the story. Personal biases of elected officials may also hinder the development of accurate perceptions. Representatives may be inclined to engage in *social projection*: projecting their own policy preferences on voters (Krueger and Clement 1994). This cognitive bias may lead representatives to overestimate support for

¹I use the terms ‘high-status voters,’ ‘affluent voters,’ and ‘privileged voters’ interchangeably to describe segments of the electorate with more political resources.

policies they themselves endorse. Social projection may result from a systematic tendency of public officials to deem opposing views as uninformed or non-salient (Butler and Dynes 2016). Hence, even without inequalities in political voice, politicians may generate images of the constituency that are tinted by their own views.

I test these expectations with surveys of elected officials in Sweden and Switzerland. Study 1 explores a six-wave panel of Swedish MPs covering two decades of elite beliefs about voters. This dataset was combined with mass surveys fielded concurrently to create measures of perceptual accuracy for 24 policy issues. The analyses reveal that elite beliefs disproportionately reflect the preferences of high-status voters. On average, the probability of an MP correctly perceiving the majority opinion on a given policy issue decreases 12 points when white-collar voters disagree with the median voter in a given party. Consistent with the mechanisms proposed, these effects are moderated by the types of groups MPs interact with – unions or business organizations –, and by the personal background of legislators. The analyses also show evidence of social projection: elected officials systematically overestimate public support for policies they personally endorse.

Study 2 was designed to explore whether the biases uncovered in the first study can be mitigated. In an original experiment that leveraged real political events, 2,917 Swiss local elected officials were asked to estimate support for two upcoming referendums in their constituencies. Together with the disaggregated results from the popular votes, these data allowed me to produce *precise* measures of perceptual accuracy at the local level. Officials were randomly assigned to informational cues designed to overcome inequalities in exposure and social projection. The probability of representatives correctly predicting majority preferences in their constituency increased 4 to 9 percentage points when encouraged to avoid availability heuristics and consider the electorate more broadly. Encouraging officials to avoid social projection, in turn, reduced the tendency to overestimate support for policies endorsed, as expected, but this effect did not improve the representatives’ ability to identify the majority opinion.

The patterns uncovered here are consistent with recent scholarship in the United States showing that political elites systematically perceive their own constituents as more conservative than they actually are (Broockman and Skovron 2018; Hertel-Fernandez et al. 2019). This conservative bias in elite beliefs can be partially explained by inequalities in political voice, since more affluent voters in the U.S. tend to be more conservative (Mendelberg et al. 2017; Suhay et al. 2020).

The study sheds light on the constraints faced by elected officials to act on behalf of those who elected them (Butler and Nickerson 2011; Pitkin 1967). The findings contribute to scholarship on political representation and elite behavior. Prior work established that affluent voters have an easier time converting preferences into policy in Sweden (Persson and Branham 2020), Switzerland (Lloren et al. 2015), and elsewhere (Adams and Ezrow 2009; Bartels 2008; Giger et al. 2012; Gilens 2009; Schakel 2019). The patterns uncovered here suggest that unequal exposure to voters can partially explain these dynamics, by producing distorted beliefs about public preferences. Hence, policy outputs can reproduce existing political and economic inequalities even when legislators are not trying to favor any particular subconstituency.

The nature of elite perceptions of public opinion

Aggregating preferences is intrinsically complex. Time-constrained politicians are exposed to a vast array of cues available through different channels: direct contacts from constituents, lobbyists, the media, social networks, political parties, or peers. To condense these overlapping demands is a daunting task, and the information available to legislators is often incomplete (Butler and Nickerson 2011; Gulzar et al. 2020; Pereira 2019). This context offers fertile ground for the adoption of cognitive shortcuts. Individuals rarely conduct extensive information searches before making judgments, particularly for complex decision-making tasks (Tversky and Kahneman 1974). Instead, they rely on a subset of *available*

information. More accessible information is more easily retrieved from memory and therefore tends to play a dominant role in individual judgments (Ajzen 1996; Carlston and Smith 1996). However, heuristics have limits. The subset of information on which individuals rely may not be representative of all the information available (Fiedler and Schmid 1995; Lodge et al. 1990).

I argue that (1) inequalities in exposure to voters, and (2) the policy preferences of legislators shape the *type of information that becomes available (more visible) to public officials*. When this subset of information is biased, it may translate into misperceptions.² *Information availability*, in this context, refers to the “ease with which instances and occurrences could be brought to mind” (Tversky and Kahneman 1974, 15). The two arguments articulated below are expected to play a central but not exclusive role in explaining misperceptions. Complementary explanations are discussed in the concluding section.

Before moving forward, I should clarify the concept of constituency adopted in the study. Constituency is defined as the group of subjects who grants authority and holds accountable an elected official or party (Rehfeld 2005). From the legislators’ perspective, it refers to any representation of the public that acts as principal in the delegation chain. Therefore, a constituency can take different shapes depending on the institutional context in which legislators operate. Common conceptualizations include geographical constituencies, party constituencies, or the electorate as a whole (Däubler 2020; Esaiasson and Holmberg 1996; Katz 2020).³ Some explanations for why legislators misperceive constituency preferences may vary according to the way a constituency is defined. However, as articulated below, I expect both sources of misperceptions proposed here to apply to different representations of the public.

²I use the terms ‘misperceptions’ and ‘biased/distorted perceptions’ interchangeably, although I recognize that the latter describe just one type of misperception. In the context of this article, both concepts refer to systematic biases in elite beliefs about the electorate, the main outcome of interest in the study.

³As Richard Katz (2020) puts it, “[i]n a democracy, the represented naturally are primarily the citizens but they can be classified in many ways [...]. Significantly, however, the particular aggregate represented in the expressive sense need not be the same, or even at the same level of aggregation, as that represented in the governing sense” (258).

Exposure and beliefs

Elected officials do not interact with all segments of their constituency in the same way. Systemic inequalities in political resources among subgroups, as well as legislators' own personal networks, shape the type of information that is more readily available.

A cross-cutting pattern in contemporary democracies is that more affluent (Gallego 2007; Schlozman et al. 2012; Verba et al. 1995), organized (Klüver 2020; Olson 1965; Schattschneider 1975), politically engaged (Galston 2001; Griffin and Newman 2005), and well connected (Campbell 2013) segments of society are more likely to make their voices heard in the policymaking process. Hence, the preferences of more privileged subconstituencies are often more salient in the public discourse. If officials rely on availability heuristics to gauge public preferences – as posited above – the positions of high-status voters may be given disproportionate consideration. There is some evidence for this argument in the American context. When Congressional staffers think about subconstituencies relevant for a given policy initiative, they are more likely to recall groups that often contact and contribute to the legislator (Miler 2007). Additionally, in recent years scholars have uncovered a conservative bias in elite perceptions of public opinion that may result from similar inequalities in exposure to voters (Broockman and Skovron 2018; Hertel-Fernandez et al. 2019).

Interest groups also shape whose opinions become more readily available to legislators (Klüver 2020). There is ample evidence of representational biases in the pressure system (e.g., Binderkrantz et al. 2015; Crosson et al. 2020). Even in organizations that represent marginalized subconstituencies, the preferences of their most advantaged members tend to prevail. Groups representing low-income people or racial minorities are substantially less active on issues affecting disadvantaged members, relative to issues affecting more privileged members (Strolovitch 2008). Hence, I expect interest groups to reproduce and amplify existing inequalities in political voice.

Information gathered through legislators' personal experience is also more accessible. Familiar information is easier to recall (Tversky and Kahneman 1974). Reviewing his expe-

rience in office, a former mayor from a suburb of Washington, D.C. illustrates this challenge: “both [factions in the legislature] may have wrongly estimated the location of the median voter – it is easy to do when one regularly receives vocal communications from your neighbors [...] on the street and in your inbox.” (Lublin 2018, 171). More broadly, researchers have noticed for decades that our social networks tint our image of the world: our political attitudes, and behavior (Campbell 2013). At the same time, in most countries policymakers are drawn disproportionately from more privileged segments of society (e.g., Carnes and Lupu 2015). If representatives use availability heuristics to gauge constituency preferences, as proposed here, they may rely disproportionately on the positions of these same privileged subconstituencies.

Together, both mechanisms suggest that the preferences of high-status voters are more visible to legislators. When the policy positions of more privileged subconstituencies are aligned with the majority, inequalities in exposure are not expected to distort perceptions of public opinion. However, when in disagreement, unequal exposure combined with availability heuristics can lead to misperceptions. Importantly, this process may take place unconsciously. It does not require any active discrimination from legislators (Butler 2014). The following implication derives from these arguments:

Exposure Hypothesis: Elected officials are more likely to misperceive public opinion when the position of high-status voters deviates from the majority.

Personal preferences and beliefs

Differential exposure is not the only source of misperceptions. Even when public opinion information is not skewed, personal biases may distort how elected officials process and incorporate constituency signals.

Gauging constituency preferences is a social inference task. A potential bias associated with this cognitive process is known as *social projection* (or false consensus bias): the propensity to overestimate the degree to which others share our attitudes and beliefs (Ross et al.

1977). Social projection is one of the most robust and well-documented social judgment biases (Mullen et al. 1985), since Katz and Allport (1931) found that students who cheated in tests systematically overestimated the share of peers who had also cheated. The tendency to project our attitudes on others is moderated by perceptions of similarity (Davis 2017) and is understood as an irrational and unavoidable behavior, rather than a result of statistical (i.e., Bayesian) reasoning (Krueger and Clement 1994). However, recent scholarship suggests that social projection can be mitigated through incentives (Epley et al. 2004) or personalized feedback (Morewedge et al. 2015).

Among political elites, there is a large amount of anecdotal evidence suggesting that representatives engage in this type of bias. In recent years, David Cameron’s decision to call a referendum on the United Kingdom’s membership in the European Union is one of the most consequential episodes resulting, in part, from false consensus bias. The British prime minister campaigned against Brexit. However, as analysts described at the time, “David Cameron underestimated the strength of Eurosceptic feeling and probably also the discredit of which his government [was] the focus” (The Robert Schuman Foundation 2016). Early scholarship on elite beliefs provides suggestive evidence in line with this view (Converse and Pierce 1986; Holmberg 1974; see also Hertel-Fernandez et al. 2019). Based on a survey of members of the European Parliament, Holmberg (1999) concluded that “[t]he unpleasant truth is that a largely irrational tendency toward wishful thinking is more significant for members’ knowledge of voter opinion than other more rational processes of knowledge acquisition” (249). These behavioral patterns may be due to a tendency of public officials to discount opinions they disagree with (Butler and Dynes 2016). Contrasting views are systematically seen as less informed, and less likely to represent the majority opinion. Hence, social projection can translate into misperceptions by altering the type of information that is most visible (or available) to legislators. These arguments suggest the following prediction:

Social Projection Hypothesis: Elected officials are more likely to misperceive public opinion when disagreeing with the majority position on a given policy issue.

As the term ‘projection’ implies, the argument suggests that legislators’ attitudes inform their beliefs about constituency preferences. There is robust causal evidence of this cognitive bias in different contexts: individuals randomly assigned to a state (an experience, opinion, or behavior), overestimate the prevalence of that state (e.g., Agostinelli et al. 1992; Krueger and Clement 1996; van Boven et al. 2000). At the same time, perceptions about others can also shape preferences, particularly when individuals hold weak or ambiguous attitudes. In the context of politicians’ beliefs about voters, I expect this alternative causal pathway to play a limited role. First, self-referent information (e.g., our personal preferences) is more accessible than estimates about the attitudes and behavior of others (Clement and Krueger 2000). Second, by the nature of their job, policymakers are more likely to hold policy preferences rooted in information and less susceptible to change. Politicians are more resistant to debiasing interventions than the general public (Christensen and Moynihan 2020). Finally, politicians often see themselves as opinion leaders and engage in efforts to shape public opinion rather than accommodating it (Gabel and Scheve 2007; Page and Shapiro 1984).

The relationship between exposure and social projection

Exposure and issue preferences are not independent from each other. Exposure can either influence or be influenced by the personal positions of legislators. Additionally, descriptive representation – to the extent that it shapes both the type of constituents with which legislators interact *and* the policies they most care about – can influence both arguments. That said, the arguments advanced above should have independent (unmediated) effects on perceptions of public opinion. The empirical strategy adopted in this study was designed to isolate these different dynamics.

To illustrate these differences, it is useful to consider how political inequality relates to each theoretical argument. According to the exposure hypothesis, inequalities in political resources produce distorted beliefs independent of the personal preferences of the legislator. On the other hand, according to the projection hypothesis, elite beliefs only reflect political

inequalities if the preferences of legislators are aligned with the position of more privileged subconstituencies (and not aligned with the majority opinion). Hence, although exposure and projection may affect each other, I expect both arguments to have independent effects on the ability of legislators to gauge constituency preferences.

Empirical Strategy

I test the main predictions derived from the theory in two complementary studies. Both studies conceptualize perceptual accuracy as the ability of political elites to correctly identify the majority position on a given issue (Pitkin 1967). Study 1 is based on a long-running panel of Swedish MPs matched with two mass surveys fielded concurrently for over two decades. To my knowledge, these data sources represent the most comprehensive effort to measure elite perceptions of public opinion. The analyses in Study 1 are designed to investigate the two main predictions derived from the theory and the mechanism underlying the exposure hypothesis.

Study 2 complements the first study through an original survey with Swiss local elected officials. I designed this study to explore whether inequalities in exposure and social projection can be experimentally manipulated. Days before two federal referendums, politicians were asked to estimate the share of voters *in their municipality* supporting each initiative on the ballot. Prior to this task, politicians were randomly assigned to informational nudges designed to induce perceptual accuracy by avoiding unequal exposure and social projection. This empirical strategy allows me to assess the extent to which biases in elite perceptions of public opinion can be mitigated.

Relying on two of the wealthiest countries in the world restricts the scope of the findings. Relative to the average elected official in Europe, Swedish and Swiss legislators may have more resources to gauge public preferences. However, both countries are also among the most socially inclusive societies in the world, making them hard cases to uncover the political

consequences of inequalities in political voice.⁴ The gaps in preferences between privileged subconstituencies and the majority tend to be starker in contexts with more income inequality (Rueda and Stegmueller 2016; Voorheis et al. 2015). Additionally, to the extent that descriptive representation can mitigate inequalities in exposure, Sweden stands out as one of the countries where MPs (relatively) better reflect the social diversity of their constituency. Scandinavian parliaments are among the most broadly based legislatures (Holmberg and Esaiasson 1996; Norris and Levendusky 1995; but see Dal Bó et al. 2019). Two features of the Swiss system may also mitigate informational asymmetries. First, the frequency of referendums and other direct democracy instruments provides regular data on voter preferences to policymakers. Second, local Swiss legislators in Study 2 are largely part-time politicians who maintain an active role in civil society, potentially facilitating exposure to different subconstituencies. For these reasons, Sweden and Switzerland represent less likely cases to identify the effects of informational asymmetries.⁵

Sweden and Switzerland have relatively influential political parties, and the decisions of individual legislators in both countries may be constrained by intraparty dynamics (Giger and Klüver 2016; Karlsson 2018; Öhberg and Naurin 2016).⁶ However, distorted beliefs about the electorate are consequential regardless of how party-centric a system is. Political parties are groups of individuals. If these individuals express similar types of biases when gauging public opinion, these biases should carry on to the collective decisions of parties. Appendices A and D provide more contextual information about Sweden and Switzerland, respectively.

⁴According to the Social Progress Index, Sweden and Switzerland are globally ranked 11th and 3rd, respectively, regarding basic human needs, foundations of wellbeing, and individual opportunity.

⁵Recent evidence from Pakistan is consistent with this perspective. In a survey of Pakistani local officials, only 59% of representatives correctly perceived the majority opinion in their constituency (Liaqat 2020). The equivalent figures for Sweden and Switzerland, as described below, are around 70%.

⁶This is less of an issue in the Swiss context, where candidates for local office often run without a party label (Ladner 2005).

Study 1: Panel of Swedish MPs

To measure elite perceptions of public opinion, I first rely on a constellation of survey data from Sweden. Since 1985, the Swedish Parliamentary Survey (RDU) has surveyed MPs once every term. For each wave of the RDU, response rates have been consistently above 90%.⁷ The panel asks elected officials their own opinions on a large set of policy issues, along with perceptions of constituency preferences on those same issues. For six waves of the parliamentary survey – 1985, 1988, 1994, 1998, 2002, and 2006 –, the Swedish National Election Studies (SNES) and the SOM Institute Surveys (SOM) asked identical policy questions to representative samples of voters in the same period.

In order to compare elite perceptions with voters’ expressed policy preferences, I combined all three datasets. Whenever the SNES and SOM conducted mass surveys concurrently, I merged the two samples. On average, the combined dataset includes 4,865 respondents per wave.⁸ With these data, I calculated different measures of policy support, as detailed below. Overall, 24 distinct policy issues were asked simultaneously in the MP and mass surveys. Additionally, on average each of the policy items was asked in three of the six matched waves. Table B1 lists all policy issues, waves and sources used in the analysis. Since the key goal of Study 1 is to explain individual variation in the ability of legislators to gauge public preferences, the unit of analysis is MP-year-policy. The combined dataset includes 22,373 individual perceptions of voter preferences.

Measuring perceptual accuracy

The main outcome of interest in the analyses reported below is a measure of perceptual accuracy. Respondents in the mass surveys were given a five-point Likert scale to answer each policy support question. In turn, MPs were asked whether a majority of their “own party’s

⁷In the six waves used in the current study, response rates were 97% (1985 and 1994), 96% (1988), and 94% (1998, 2002, and 2006) (Karlsson and Nordin 2015). Given the nearly complete coverage of the survey, full access to the datasets is restricted to the precincts of the University of Gothenburg.

⁸ Combined sample sizes by wave: 4,365 respondents in 1985, 4,135 in 1988, 3,996 in 1994, 5,340 in 1998, 6,184 in 2002, and 5,170 in 2006.

voters” supported a given policy. In the Swedish context, the party base is considered the most relevant constituency for representatives (Esaiasson and Holmberg 1996).⁹ To combine the two measures, I dichotomized public support.¹⁰ *Perceptual Accuracy* takes the value of 1 if an individual MP correctly identifies the majority opinion among party voters, and 0 otherwise.¹¹

The average value of *Perceptual Accuracy* is 0.73. From 1985 to 2006, Swedish MPs correctly perceived the majority opinion in their party constituency 73% of the time. To provide a more detailed description of the variable, Figure 1 plots average values of perceptual accuracy by issue (gray lines) and for all issues asked in a given year (green line). Two patterns are worth noting. First, although perceptual accuracy is generally high, there is considerable variation across issues and over time. While 92% of MPs correctly perceived the majority opinion on the expansion of privately-run health care in 2006, over 60% of representatives *misperceived* voters’ opinion on whether to decrease defense spending in the same year. Second, there is a gradual decline in perceptual accuracy over the two decades covered. Since this pattern may be simply due to the type of issues asked in each wave,

⁹This pattern is not specific to party-centric systems. Lax et al. (2019) recently uncovered similar dynamics in the American context. In the United States, members of Congress mainly respond to the preferences of their own party constituency. Still, to assess the sensitivity of the findings to this type of constituency, I replicated the main analyses with perceptions of the electorate as a whole (and not just the party constituency). These items are only available in the 1985 wave of the parliamentary survey. Besides the loss in scope, the same results are obtained (Table C4). Additionally, I extended the analyses from Hertel-Fernandez et al. (2019) to provide an out-of-sample test of the same hypotheses using the electorate as the reference constituency. The analysis reported in Appendix H shows that perceptions of electorate preferences among Congressional staffers are also swayed by high-status voters and egocentric biases. Together, the results suggest that the theoretical arguments advanced here are not contingent on the definition of constituency adopted.

¹⁰Majority support takes the value of 1 if over 50% of party respondents stated that a policy proposal was “very good” or “fairly good”, and 0 otherwise. Voters without an opinion on a given policy are proportionately distributed among supporters and opponents. However, the same results are obtained when the share of supporters is calculated with undecided respondents in the denominator (Table C5), or when taking into account gradations of accuracy based on the distribution of constituency preferences (Table C6).

¹¹A potential concern with this empirical approach is that once the mass public samples are split into party constituencies, we can no longer ensure that the average levels of support for each party are representative. Given the large sample sizes (see fn. 8) and the relatively small number of sub-groups (7 parties), the magnitude of the biases resulting from disaggregating the sample are potentially limited. Still, I re-estimated the main models with bootstrapped standard errors to incorporate uncertainty from the public opinion estimates. The same patterns are uncovered (see Table C7). The results are also robust to analyses considering *only* MPs from smaller parties, for whom the estimates of partisan policy support may be more prone to measurement error due to smaller sample sizes (see Table C8).

Figure 1: Average perceptual accuracy by wave of parliamentary survey.

Note: “All issues” includes data from all 24 policy issues asked in the different waves. “1985-2006 issues” only includes issues asked in at least five of the six waves, including 1985 and 2006: reduce public sector, reduce defense spending, more private health care, prohibit all kinds of pornography, and the introduction of 6-hour working days.

Figure 1 also plots averages for the five issues that were asked consistently from 1985 to 2006 (orange line). The same general pattern is observed for this constant set of issues. Average perceptual accuracy among common issues went from 78.2% in 1985 to 65.4% in 2006. It is beyond the scope of this project to explain this pattern. Still, it suggests that the ability of elected officials to gauge constituency preferences is dynamic.

The MP survey asked legislators about the preferences of their party constituency: voters who supported their party in the most recent election (2-4 months earlier). In performing this task, it is possible that politicians thought about different party supporters such as party members (Dalton 1985; Scarrow and Gezgor 2010; but see van Biezen and Poguntke 2014). While this could be consistent with the exposure hypothesis, it is important to note that in Sweden “party members resemble party voters to a high degree [...] Nordic parties have maintained a high level of representativeness when looking at the social composition of their membership” (Heidar et al. 2019; 93). Polk and Kölln (2019), in turn, report high

levels of within-party congruence among party members, party voters, and party candidates in Sweden. Mass surveys corroborate these conclusions. In Figures B2-B5 I compare the demographics of party sympathizers and party voters with verified turnout. The two groups are very similar along the different dimensions used to identify high-status voters. This is likely due to the high levels of turnout in Swedish elections, between 80 and 90% in the period covered. In this context, thinking about different types of party constituencies – sympathizers, voters, or members – is unlikely to bias the results in a relevant way.

Research Design

If exposure shapes perceptions of constituency preferences, as articulated above, elected officials should give disproportionate weight to the preferences of high-status voters. High-status voters are segments of the constituency with more political resources. These resources affect the ability of voters to make their voices heard in the policymaking process (e.g., Schlozman et al. 2012) and can be materialized in different ways: actual financial resources, organizational capacity, or accessibility to legislators (from common social networks or geographical proximity). To capture the multidimensional nature of high-status voters, I use four complementary variables: occupational social class, education, income, and place of residency. Social class is simultaneously a strong indicator of political resources and a meaningful political cleavage for both voters and politicians (Evans 2000; Carnes and Lupu 2015). Income and education, on the other hand, capture more directly individual resources and political influence. Finally, place of residence captures connectedness and access to the political sphere more broadly (Busch and Reinhardt 2005; Tavits 2005). Descriptive statistics for all variables included in the analysis are described in Appendix B.

To produce measures of policy support for different subconstituencies, I recoded each variable as follows. Occupational social class was split into three categories: blue-collar (40.6%), white-collar (42.3%), or other. Educational attainment was classified as low (1-9 grades or less; 31.4%), medium (above comprehensive school but no college; 39.6%) or

high (college degree; 30.0%). The measure of income is based on a distributional scale of household income validated by the Swedish register. From the original variable, I created three categories: low income (15th income percentile or lower); high income (85th percentile or higher); and medium income for the remaining subjects. Finally, place of residence is divided in two categories: respondents from rural areas and villages (42.4%), and respondents from cities (57.6%).¹²

Based on these typologies, I re-calculated policy support *exclusively among high-status partisans*: (1) white-collar, (2) high education, (3) high income, or (4) urban voters. Finally, for each policy item I created a binary variable capturing opinion disagreement between high-status party constituents and the majority of copartisans.¹³ This process leads to four complementary predictors: one per measure of high-status. As an example, consider the case where high-status is captured through social class. The variable takes the value of 1 for a given MP from party X if white-collar copartisans disagree with the majority of party X voters on a given policy issue, and 0 otherwise. According to the exposure hypothesis, legislators are more likely to misperceive public preferences when the position of more privileged subconstituencies deviate from the majority.

To capture the propensity for social projection, in turn, I contrast the self-reported preferences of MPs with constituency preferences on the same policy. *MP and Voters dealigned* is a binary variable that takes the value of 1 if an MP disagrees with the majority of party constituents (either supporting or opposing the policy), and 0 otherwise.

The distribution of constituency preferences is likely to affect both the key predictors of interest in the analysis and perceptual accuracy. Hence, all models account for *preference imbalance*: the absolute difference between the share of constituents supporting or opposing a given policy. Smaller values suggest a more balanced distribution of preferences, which should be associated with less perceptual accuracy. Additionally, the models account for

¹²Table B2 describes the bivariate correlations between the different variables. Although all four variables are positively correlated, correlations are moderate to small (Pearson's r between 0.08 and 0.35). This suggests that the variables indeed capture different types of political resources.

¹³The majority includes all party constituents, regardless of levels of affluence.

two individual features of the MPs that may shape their capacity to gauge constituency preferences: policy expertise, and experience in office. Expertise is based on committee membership. To create this measure, I matched each policy issue available in the dataset to one of the Riksdag committees in place during the respective term. *Expertise* takes the value of 1 if the MP belongs to the committee associated with a given policy, and 0 otherwise. *Experience in office* is captured by the logged number of terms in office.

The final dataset includes several sources of variation: across time, parties, policies, and individual MPs. I am interested in capturing individual-level variation in the capacity of MPs to gauge constituency preferences. Hence, the models include fixed effects to account for any systematic differences across time, party, or policy. Finally, because each individual MP enters the dataset multiple times (once per policy issue in a given wave, and eventually across waves), all models include cluster-robust standard errors by individual MP. The same results are obtained when the models alternatively include fixed effects by individual MP (Table C3).

Results

As a starting point for the analysis, Figure 2 describes levels of alignment between perceptions of public opinion and the preferences of high-status and low-status voters. The x -axis describes how the different subconstituencies are measured in each pair of estimates. Perceptions of public opinion among Swedish legislators are consistently better aligned with the preferences of high-status voters. With the exception of income, the differences in agreement between high- and low-status constituents are distinguishable from zero at conventional levels (p -values < 0.05) and range from 4 to 7 percentage points. This descriptive pattern provides initial evidence that elite beliefs disproportionately reflect the position of more privileged groups.

Figure 3 reports the main results from Study 1. The estimates for each of the key predictors (listed on the y -axis) were derived from linear probability models with *Perceptual*

Figure 2: Share of policies where MP majority perceptions align with high-status/low-status voter preferences.

Note: Each bar represents the share of policy assessments in the parliamentary survey where MP perceptions of constituency preferences aligned with the majority opinion among different operationalizations of high/low-status voters (described along the x -axis).

Accuracy as the outcome. The predictor *High-Status* $\neq$ *Majority* captures instances where high-status voters deviate from the majority opinion on a given policy issue. Each color represents a pair of estimates from a different model, based on the measure of high-status voters adopted. The results provide support for the two main predictions derived from the theory and are robust across measures of political resources.

Disagreements between high-status voters and the majority of party constituents are associated with *lower* perceptual accuracy. The effects are substantively meaningful. As an example, when white-collar voters disagree with the majority on a given issue (green estimates), the probability that MPs correctly perceive majority preferences is 12 percentage points lower. Importantly, these effects imply that *legislators are replacing the position of the majority with the position of more privileged subconstituencies*. Consider an instance where the majority *supports* a policy but white-collar voters oppose it. In this case the predictor takes the value of 1. The negative coefficient means that legislators are more likely to (incorrectly) claim that the majority opposes the policy when white-collar voters

Figure 3: The role of high-status voters and MP personal preferences on perceptual accuracy.

Note: Dots are estimates from linear probability models with perceptual accuracy as the outcome variable. Horizontal lines represent 95% confidence intervals. The main predictors are listed on the y -axis. Each color represents a different model based on the operationalization of high-status voters. Full model results in Table C1.

also oppose it. Hence, perceptions of majority preferences follow the position high-status constituents.

A similar pattern is observed when *high-education* voters disagree with the majority (point estimate = -0.11 ; s.e. = 0.01). While occupational social class and educational attainment are positively correlated (Pearson's $r = 0.28$), only 47.2% of self-identified white-collar respondents were also classified as high-education. Hence, the two constructs are not capturing the same subconstituency. Finally, the effects of policy disagreement for high-income voters are also statistically significant and in the expected direction, but smaller in magnitude (point estimate = -0.04 ; s.e. = 0.01).¹⁴

The models also provide support for the social projection hypothesis. Returning to the social class model (green estimates), the coefficient for $MP \neq Majority$ suggests that when

¹⁴As a robustness check, I reestimated the main models using gender as an indicator of high-status voters. Although Sweden is ranked among the most gender egalitarian countries in the world, important inequalities persist (Besley et al. 2017; Folke and Rickne 2020). Consistent with the exposure hypothesis, perceptual accuracy decreases when male constituents disagree with the majority. The same is not true for female constituents (Table C2).

MPs support/oppose a policy that is opposed/supported by the majority of party voters, the probability of correctly perceiving constituency preferences decreases 38 points. The estimated effects of social projection are sizeable.¹⁵ Holding the remaining variables at their medians, the predicted probability of correctly identifying the majority opinion on a given issue goes from 0.90 when MPs agree with their party constituency, to 0.52 when MPs disagree. According to the model, the chances of dealigned MPs correctly perceiving copartisan preferences are close to a coin toss.

Importantly, these results are obtained accounting for preference imbalance within each party constituency. Opinion dealignment between voters and MPs is more likely when public opinion is evenly split on a given issue. However, all models account for the absolute difference between copartisan supporters and opponents in a given policy. The results are also not explained by time-invariant differences across legislators. As reported in Table C3, the same patterns are uncovered when the analyses include fixed effects by individual MP ($N = 1,069$).

A question that remains open is whether the effects of high-status voters disagreeing with the majority are unique to more privileged groups. It is possible that the patterns observed mainly capture instances where the distribution of voter preferences is wider, or less crystallized. In this context, it is both more likely that (1) some segments of the electorate have a distinct opinion from the majority, and (2) that perceptual accuracy is lower, since gauging policy preferences can be more challenging. To assess this alternative explanation, I reestimated the main models replacing *High-Status $\neq$ Majority* with measures of opinion disagreement between low-status voters and the majority.¹⁶ If the patterns observed above result from the lack of opinion crystallization, we should observe similar effects for privileged and less-privileged voters. The results reported in Figure C1 do not support this argument.

¹⁵The effect sizes are comparable to prior research (e.g., Converse and Pierce 1986). In the American context, Congressional staffers who supported a given salient policy estimated public support to be 17 to 36 percentage points higher, on average (Hertel-Fernandez et al. 2019).

¹⁶Low-status voters are identified as (1) blue-collar workers, (2) respondents with the ninth grade or less, (3) respondents in the 15th income percentile or lower, or (4) respondents living in villages or rural areas.

Across specifications, the coefficient for disagreement between low-status voters and the majority is either indistinguishable from zero or in the opposite direction of what we would expect.¹⁷

In sum, the analyses suggest that differential exposure and social projection are relevant drivers of elite misperceptions. When high-status voters (and *not* low-status voters) disagree with the majority, legislators are systematically less likely to correctly gauge constituency preferences. In turn, when legislators themselves disagree with constituents on a given issue, their ability to identify the majority opinion is meaningfully curtailed.

Mechanism test: MP behavior and personal background

So far, the analysis suggests that Swedish MPs tend to rely disproportionately on the positions of high-status voters when gauging public opinion. This may be happening for a number of reasons. I argue that this pattern results from biases in exposure to different subconstituencies.¹⁸ If this mechanism is correct, we should expect the weight attached to the opinions of more privileged voters to vary according to (1) the active decisions of MPs to engage with different groups, and (2) the idiosyncratic background of legislators.

To test the plausibility of this mechanism, I conducted two additional analyses. First, I reestimated the main model reported above, but conditioning *White-Collar* $\neq$ *Majority* on how often MPs report meeting with (1) blue-collar unions (members of the *Landsorganisationen i Sverige*), and (2) private businesses and business organizations.¹⁹ If the exposure

¹⁷Table C11 provides an alternative modelling strategy to test the exposure hypothesis interacting high/low-status voter preferences with the size of the gap in preferences between subconstituencies. Consistent with the exposure hypothesis, only the effect of low-status preferences on elite perceptions decreases as the preference gap increases.

¹⁸An alternative mechanism is that legislators are actively giving more weight to the preferences of high-status voters with the expectation that this may help them in their reelection efforts (e.g., through donations), or in their post-legislative careers. The analyses conducted in this section only partially rule out this mechanism. However, the results in Study 2 are not consistent with this alternative story. If legislators were strategically misperceiving public opinion, encouraging them to develop more accurate perceptions of voter preferences should not lead to a decrease in misperceptions. This issue is further discussed in the concluding section.

¹⁹These variables are based on two items from the RDU surveys asking MPs how regularly they interacted personally, or by letter, with a variety of different organizations. Responses are recorded on a five-point

hypothesis is correct, we should expect the capacity of white-collar preferences to sway elite perceptions of public opinion to *decrease* with the regularity of contacts with blue-collar unions. The opposite pattern would be expected for contacts with business organizations.

Figure 4 provides suggestive evidence in line with this argument. Panel (a) reports the marginal effects of white-collar voters disagreeing with the majority on a given issue, conditional on MPs' self-reported contacts with blue-collar unions. The distribution of the conditioning variable is described along the x -axis and reveals appropriate common support for most of the scale. As expected, the weight of white-collar voter preferences is *smaller* among legislators with more exposure to blue-collar unions (p -value for interaction term = 0.05). According to the model, when white-collar voters disagree with the majority, the probability that an individual MP *who never contacts blue-collar unions* correctly identifies the majority position decreases 18.1 percentage points. The same effect for MPs *who interact with unions once or twice a month* decreases to 11.6 points. The opposite pattern is observed for interactions with business organizations (Panel (b); p -value = 0.08). Regular contacts with businesses are associated with a heightened weight of white-collar preferences.

Next, I explore how the personal background of MPs can moderate exposure to different subconstituencies. I consider the role of MPs' (1) occupational class prior to joining parliament, (2) educational background, and (3) place of residence growing up.²⁰ The expectation is that the preferences of *high-status* voters carry less weight among legislators with less privileged backgrounds: non-white-collar MPs (53.1% of the sample), MPs without a college degree (43.1%), and MPs with a rural background (51.4%).

The analyses reported in Figure 5 provide partial support for this prediction. Each panel reports the marginal effects of high-status voters disagreeing with the majority, conditional on MPs' (a) social class, (b) educational background, and (c) geographical background. The operationalization of high-status voters in each model matches the specific background

labeled scale from 'Never' to 'At least once a week'.

²⁰The income levels of MPs are not available in the RDU surveys. However, I believe that the remaining measures properly capture the background of MPs.

Figure 4: The marginal effects of white-collar voters disagreeing with the majority on perceptual accuracy, conditional on MP contacts with (a) blue-collar unions, and (b) businesses.

Note: Dots are marginal effects of white-collar voters disagreeing with majority on perceptual accuracy, conditional on the regularity of contacts with blue-collar unions (panel a), and businesses (panel b). Vertical bars are 95% confidence intervals. Numbers along x -axis describe the distribution of the conditioning variable. See Table C9 for full results.

feature of the MPs and is described on the y -axes. Across specifications, the results suggest that legislators with less privileged backgrounds are *less likely* to rely on the positions of high-status voters when gauging constituency preferences. The effects are reliable for educational and geographical background. As an example, the estimates in panel (c) suggest that, when urban voters disagree with the majority, perceptual accuracy decreases on average 12.4 points *among MP with an urban background*, but only 7.5 points among MPs with a rural background (p -value of interaction term = 0.02). The results are consistent with research on the substantive impacts of descriptive representation (Carnes and Lupu 2015).

Together, the analyses provide evidence for the mechanism underlying the exposure hypothesis. Both the behavior of MPs in office (Figure 4) and their idiosyncratic background (Figure 5) shape the type of information used when gauging constituency preferences.

Figure 5: The marginal effects of high-status voters disagreement on perceptual accuracy, conditional on MPs (a) class background, (b) educational background, and (c) geographical background.

Note: Dots are marginal effects of high-status voters disagreeing with majority on perceptual accuracy, conditional on the MP's class (panel a), educational (panel b), or geographical (panel c) background. The operationalization of high-status voters in each model is described along the y -axis and was chosen to be consistent with the moderator. Vertical bars are 95% confidence intervals. Numbers along the x -axis describe the distribution of the conditioning variable. See Table C10 for full results.

Study 2: Experiment with Swiss local officials

The previous study revealed two sources of bias in elite perceptions of public opinion: inequalities in exposure, and social projection. I conducted Study 2 to assess whether these biases can be minimized. Can public officials be encouraged to develop more accurate beliefs about their constituencies?

The analyses are based on an original survey of Swiss local elected officials leveraging real political events. Switzerland offers a unique opportunity to study elite perceptions of public opinion due to the large number of popular votes held every year. By conducting a survey of local representatives prior to a set of referendums, I was able to compare elite perceptions of constituency support for different issues with *accurate* behavioral measures of policy support at the municipal level.²¹ Two advantages result from this empirical strategy. First, it allows me to go around measurement issues associated with calculating preferences

²¹I use the terms 'referendum' and 'initiative' interchangeably. However, in Switzerland there is distinction between initiatives (proposals initiated by citizens), and referendums (mandatory or optional). The two specific issues included in this study are popular initiatives.

for subnational constituencies. Second, since voter preferences are measured through referendum outcomes and politicians were asked to anticipate these same results, evidence for the exposure hypothesis cannot be explained by officials *deliberately* discounting the position of less privileged subconstituencies because they are less likely to vote. Considerations about who turns out are embedded in the task.

I recruited public officials as part of the 2017 National Survey of Local Executive Members (NSLEM), a large survey covering roughly 60% of the population of Swiss local elected officials (Steiner et al. 2019).²² A total of 5,240 participants provided their contact information to take part in a follow-up study. From this pool, 2,917 officials completed the online survey administered through Qualtrics (56.7% response rate).²³

The survey was fielded in November 2018, two weeks before a set of federal referendums.²⁴ The questionnaire and all communication materials were translated to Swiss German, Swiss French, and Swiss Italian.²⁵ The key goal of the survey was to capture elite perceptions of *local public support* for a series of popular initiatives voted on that occasion. Respondents were asked to predict the share of voters in their constituency who would support two distinct referendums: the self-determination initiative and the horned-cow initiative. The first referendum, initiated by the nationalist Swiss People’s Party (SVP), proposed an amendment to the constitution that would give primacy to the Swiss constitution and popular votes over international treaties. The issue attracted substantial public attention and reached record levels in campaign spending (up to CHF 8 million, or \$8M).²⁶ The Horned-Cow initiative, on the other hand, was a low salience issue. The proposal sought to prevent farmers, through

²²More information available at: <https://www.ipm.swiss/gemeinde/>.

²³Table E1 summarizes the demographic characteristics of the sample, and compares it with the 2017 NSLEM. There are no meaningful differences across the two samples in terms of individual characteristics of the subjects, or sociopolitical features of the municipalities represented in each sample.

²⁴The median local official completed the survey in the first two days, and 75% by the fifth day since the invitations were sent. Still, there is some variation in the timing of survey completion that could affect their capacity to gauge voter preferences. Table F3 shows that the timing between survey completion and the referendums did not affect the study results in a meaningful way.

²⁵An English translation of the questionnaire is provided in Appendix G, along with the informed consent.

²⁶https://www.swissinfo.ch/eng/vote-november-25--2018_hotly-debated--swiss-law-first--initiative-awaits-public-verdict/44559238.

federal subsidies, from opting to keep hornless animals (VOTO 2019).

Experimental Design

Respondents were asked to predict the share of voters *in their constituency* who would support each referendum.²⁷ Prior to the prediction tasks, officials were randomly assigned to one of three groups.²⁸ A control group received no additional information. After reading a description of each referendum, officials in this group were directly asked to anticipate the outcome of the popular vote in their municipality. Two other groups were presented with vignettes designed to *increase perceptual accuracy*, based on my theoretical predictions.

Exposure condition: This group received information about the composition of the electorate in their municipality. The goal of this intervention was to encourage local officials to avoid potentially skewed availability heuristics resulting from inequalities in exposure. To do so, respondents took part in a three-stage task. First, they were asked to guess the prevalence of different segments of the electorate in their constituency (e.g., foreign-born citizens, supporters of the Green party). This information was recorded and reported on the following page of the survey along with the official data from the Federal Statistical Office for their municipality, and for Switzerland as a whole. Finally, officials were asked to take this information into account when making their referendum predictions. Figure E1 provides a specific example of the vignettes.

The type of information provided varied according to the referendum. To ensure that this information was informative, pre-tests assessed the predictive power of different indicators on support for similar referendums voted in the recent past.²⁹ For the self-determination initiative, officials were presented with data on the share of foreign-born citizens and SVP

²⁷In Switzerland, nationally representative polls are regularly published in the weeks leading to referendums. However, these polls do not provide municipal-level estimates. Hence, local officials could not simply rely on existing survey data.

²⁸The main hypotheses of the study were pre-registered in EGAP: <http://egap.org/registration/5322>.

²⁹Interviews with Swiss direct democracy scholars and pre-analyses of VOTO, the post-referendum surveys (VOTO 2019), informed the selection of past referendums used for the pre-tests.

supporters in their municipality. For the horned-cow initiative, the information provided was the combined share of SP and Green party supporters in the constituency, and the share of workers in the primary sector.

Exposure & Self-Awareness condition: The third group received the same informational treatment provided to the second group plus a recommendation to avoid projecting their own preferences on constituents. Box 1 provides the exact wording of the vignette. Recent scholarship suggests this type of feedback is the most effective way to mitigate social projection (Morewedge et al. 2015).³⁰

The expectation is that officials in the exposure condition should be more likely to correctly perceive the majority opinion in their constituency, relative to officials in the control condition. In turn, subjects who received the self-awareness intervention should be less likely to project their preferences on constituents, and more likely to correctly perceive majority preferences (relative to the second group). To avoid contagion effects, randomization was made at the respondent level, and the order of the referendums was randomized. Finally, I used multivariate continuous blocking to maximize balance between conditions on (1) partisanship, (2) language (German, French, or Italian), (3) municipality size (population), (4) canton, and (5) local support for the SVP and the Social Democratic Party (SP) in the previous general election. Table E2 reports covariate balance tests.

Box 1: Self-awareness vignette.

Decades of research show that people tend to project their own preferences to others. **Without noticing, we often overestimate approval for issues we support, while underestimating approval for issues we oppose.** Try to take this into account when making your prediction.

³⁰I favored a cumulative treatments design over a full factorial design to maximize statistical power. To my knowledge, Swiss local officials had never been invited to an academic online survey before. Hence, it was impossible to anticipate the sample size that would be obtained.

Results

On November 25th, 2018, Swiss voters rejected both initiatives. Nationwide, 33.8% of voters supported the self-determination initiative, while 45.3% supported the horned-cow initiative. However, there was considerable variation across municipalities. Local support for the self-determination initiative, for instance, ranged from 12.5 to 83.7%. Figure E2 describes the distributions of local-level support for each referendum.

I combined these expressed preferences with the survey results to build a measure of *Perceptual Accuracy*. The variable takes the value of 1 if a local official correctly perceived the majority position in his or her constituency, for a given initiative, and 0 otherwise.³¹ On average, Swiss local officials correctly identified the majority position in their constituency 72% of the time.³² This figure represents a relatively high baseline, potentially resulting from the small size of Swiss local constituencies and the wealth of information provided to public officials by the regular referendums.

However, the interventions improved perceptual accuracy upon this baseline. Figure 6 presents the results of three linear probability models with *Perceptual Accuracy* as the outcome variable. Coefficients for each treatment condition (described along the *y*-axes) represent the average difference in the probability of correctly perceiving local majority support, relative to the control group.³³ Panel *a* (from Figure 6) reports the treatment effects for the self-determination initiative. On average, local officials who received information on electorate composition (the *exposure group*) were 6.4 percentage points more likely to correctly identify the majority position in their constituency, relative to the control group. This effect is statistically significant (p -value = 0.002) and substantively meaningful. It represents an

³¹I relied on a binary outcome for two reasons. First, I believe it better captures the key goal of grasping constituency preferences. While it might be helpful for elected officials to know the precise share of voters supporting a given policy, most models of representation mainly expect representatives to know the majority opinion in their constituency (Downs 1957; Katz 2014; Pitkin 1967). Second, this measure is consistent with the outcome variable used in Study 1 (Figure 3, above). The results for each individual initiative are substantively similar when an absolute measure of misperceptions is used instead (Figure F1).

³²The average values for the self-determination and horned-cow initiatives are 0.71 and 0.74, respectively.

³³Table F4 replicates these models with the subset of respondents who passed the manipulation check at the end of the survey. The same results are obtained, and the magnitude of the effects increases, overall.

Figure 6: The effects of exposure and self-awareness to social projection on perceptual accuracy, by referendum.

Note: Points are estimates of the difference in the probability of local officials correctly perceiving the expressed preferences of the majority of voters in their constituency by treatment condition (control = baseline, and treatment groups described in the row labels). Wider/Thinner horizontal lines are 95/90% confidence intervals. See Table F1 for full results.

8.9% increase in perceptual accuracy, relative to the mean value of the outcome.³⁴ This pattern is in line with the theoretical predictions. When representatives are encouraged to avoid availability heuristics and consider their constituency more broadly, perceptual accuracy increases. The effect of the *Exposure & Self-Awareness* intervention, in turn, is also positive and reliable (point estimate = 0.04; p -value = 0.04). However, the effect is indistinguishable from the *Exposure* condition (p -value = 0.31). The analysis provides no evidence that encouraging political elites to avoid social projection increases perceptual accuracy.

The results for the horned-cow initiative (Panel *b*) are less conclusive. The estimates for *Exposure* (.03) and *Exposure & Self-Awareness* (.02) are positive, as expected. However, the differences in the probability of correctly perceiving majority support are indistinguishable from zero at conventional levels of statistical significance. The analysis does not allow me to rule out small differences. Still, if anything, the treatment effects for this initiative were fairly small in magnitude.³⁵ Finally, Panel *c* presents the pooled treatment effects on perceptual accuracy. This analysis includes fixed effects by initiative to account for any systematic

³⁴The average value of *Perceptual Accuracy* for the self-determination initiative was 0.72. Hence: $(.064/.72)*100 = 8.9\%$.

³⁵Formally exploring treatment heterogeneity by issue salience is beyond the scope of this study. However, it is possible that the lower salience associated with the horned-cow initiative may explain these results.

differences between referendums, and cluster-robust standard errors by local official. The results are consistent with the patterns observed for the self-determination initiative. The average differences in perceptual accuracy for officials in the *Exposure* and *Exposure & Self-Awareness* conditions are 0.05 (s.e. = 0.01) and 0.03 (s.e. = 0.01), respectively.

Together, the results show that the exposure intervention effectively increased perceptual accuracy. However, the manipulation designed to encourage legislators to avoid social projection did not meaningfully alter how elected officials gauged public opinion. On average, officials who received the self-awareness vignette were not more likely to correctly perceive the majority opinion. This result is consistent with previous failed efforts to mitigate social projection in different contexts, through perspective taking or feedback (Krueger and Clement 1994).

A question that remains open is whether the self-awareness intervention shaped the propensity of local officials to project their own preferences on constituents. To test this intermediate step, Figure 7 shows the results of linear models predicting perceived public support as a function of personal support (binary), interacted with the *Exposure & Self-Awareness* condition. The models omit officials in the control group to isolate the effect of the self-awareness intervention, by comparing the two treatment groups directly. The estimates in each panel are the coefficients of legislator support on perceived public support, for respondents in each treatment group (described in the *y*-axes). Representatives in both conditions engaged in some degree of social projection. Regardless of treatment condition, the point estimates are positive and reliable. Legislators who supported a given issue perceived public support for that issue to be systematically higher.

However, subjects who received the self-awareness vignette were significantly *less likely* to project their own preferences on voters. The differences in point estimates are reliable in all specifications at conventional levels of statistical significance (*p*-values of 0.046, 0.04, and 0.005, respectively). The intervention reduced the propensity of legislators to project their preferences on voters, but this incentive was not enough to improve their ability to

Figure 7: The effects of self-awareness on the propensity of legislators to project their preferences on the electorate, by referendum.

Note: Points are estimates of the effect of policy support on perceptions of public support, by treatment group (described in the row labels). Wider/Thinner horizontal lines are 90/95% confidence intervals. Control group omitted from the analysis to isolate the effect of the self-awareness intervention. Full model results in Table F2.

correctly identify the majority opinion. A potential explanation for this result is that social projection only translates into misperceptions when officials disagree with voters on a given issue, and roughly two thirds of local officials in the study sided with the majority of their constituency in each issue. An alternative explanation is that the combined intervention was too demanding and encouraged satisficing.

Discussion

This project explores how elected officials build their image of the constituency. I argue that inequalities in political voice and personal biases of elected officials play an important role in explaining misperceptions. Consistent with these arguments, Study 1 shows that Swedish MPs rely disproportionately on the positions of more privileged subconstituencies. A propensity for legislators to overestimate support for policies they themselves endorse is also a powerful predictor of misperceptions. Next, I explore the degree to which these biases can be experimentally reduced. In a survey with nearly 3,000 Swiss local officials, respondents were asked to anticipate the outcome of two federal referendums in their constituency after being assigned to different informational nudges. The results show that misperceptions can

be reduced by encouraging representatives to avoid inequalities in exposure.

The Swedish and Swiss studies were designed to complement each other. For instance, Study 1 allows for the possibility that politicians misperceive constituency preferences simply for strategic reasons: either because some groups matter more for reelection, or because politicians derive utility from appearing in line with voters (halo effects). However, if this was the case, the informational cues in Study 2 should not affect perceptual accuracy. The Swiss study allows me to conclude that strategic considerations cannot fully account for the patterns observed.

Still, there are specific limitations that are important to emphasize. First, in Study 1 it is not possible to ensure that the measures of party constituency preferences are representative. The robustness of the findings among smaller parties, the electorate as a whole in 1985, and accounting for uncertainty in public opinion estimates mitigate these concerns. Still, more flexible measurement models that allow subsampling based on different political dimensions would represent a major contribution to the literature. What best represents a constituency for legislators in different European countries also remains an open question. In Study 1, *party voters* were defined as the key constituency for Swedish legislators, while in Switzerland the reference constituency was the group of voters who turned out in the referendums. The consistent results across studies, as well as in the United States (see Appendix H), suggest that the sources of misperceptions identified here may operate in similar ways regardless of how a constituency is defined. Still, a better understanding of how constituencies are defined in the eyes of representatives would represent a major contribution to the field. Relatedly, the study builds upon a model of representation where all opinions in the constituency are weighed equally (Katz 2014). However, politicians may care less about voter preferences over policy and more about issue salience, policy outcomes, or the groups most affected by a given policy. Future contributions would benefit from exploring the implications of inequalities in exposure and egocentric biases in different models of representation. The study is also unable to identify the specific types of resources that better explain inequalities in political voice.

Understanding which specific resources have more impact on perceptions of public opinion would help shed light on the underlying mechanisms of this relationship.

The findings have several implications for the study of political representation and elite behavior. On the one hand, the study reveals one way through which inequalities in political voice constrain the prospects of democratic representation. The study joins recent work in the United States uncovering relevant distortions in elite perceptions of public opinion (Broockman and Skovron 2018; Hertel-Fernandez et al. 2019). However, Sweden and Switzerland are two of the most socially inclusive societies in the world. The fact that in both countries inequalities in political voice seem to have such meaningful effects on elite perceptions of public opinion is concerning. The findings shed some light on the path yet to cover until societies are able to sustain fully inclusive institutions. On the other hand, the Swiss study suggests that misperceptions are not unsurmountable. Encouraging legislators to avoid availability heuristics induced more accurate beliefs about voters. Although more research is needed to confirm the robustness of these findings, they suggest that improving perceptions of public opinion is possible even with low impact interventions.

The findings also contribute to scholarship on descriptive representation. Recent work shows how the social and professional backgrounds of politicians shape their behavior in office, even in party-centric systems (Carnes and Lupu 2015; Carnes 2013). The patterns reported here provide two novel explanations for this relationship. First, politicians with less privileged backgrounds can be less susceptible to inequalities in exposure. Second, to the extent that shared backgrounds are associated with shared preferences, social projection can lead legislators to overestimate support for different policies, according to their individual milieu. Either mechanism can shape perceptions of public opinion without the active awareness of legislators, pushing them to pursue different policies while in office.

Finally, the Swiss experiment has the potential to pave the ground for new behavioral research with political elites. So far, this nascent area of research has focused on uncovering biases in elite behavior: instances where the decisions of legislators deviate from rational

choice predictions (Esaiasson and Öhberg 2019; Sheffer et al. 2018), or from normative understandings of the democratic process (Costa 2017; Kalla and Broockman 2016; Pereira 2021). A natural next step is to use this information to provide tools for elected officials to overcome those biases, as the Swiss experiment exemplifies. The results reveal how theory-driven interventions can encourage politicians to develop more accurate beliefs about their constituents. These findings are likely context- and design-dependent. Kalla and Porter (2020) provide less optimistic findings among state legislators in the United States. Future research should further investigate when and why are elected officials willing to update their beliefs about mass preferences.

Appendix B - Study 1: Descriptives

- **Table B1:** Policy issue questions concurrently asked in elite and mass surveys, and share of voters supporting each policy by year.
- **Table B2:** Correlations between measures of affluence in mass survey.
- **Table B3:** Descriptive statistics of key variables in MP-policy dataset.
- **Figure B1:** Distribution of demographics among the electorate as a whole and party supporters.
- **Figure B2:** Occupational social class distribution among party sympathizers (green) and party voters with verified turnout (orange).
- **Figure B3:** Education distribution among party sympathizers (green) and party voters with verified turnout (orange).
- **Figure B4:** Income distribution among party sympathizers (green) and party voters with verified turnout (orange).
- **Figure B5:** Distribution of place of residence among party sympathizers (green) and party voters with verified turnout (orange).

Appendix C - Study 1: Additional analyses

- **Table C1:** The role of high-status voters and MP personal preferences on perceptual accuracy. Complement to Figure 3.
- **Table C2:** The effects of male and female voters’ disagreement on perceptual accuracy.
- **Table C3:** Determinants of perceptual accuracy, with fixed effects by individual MP.
- **Table C4:** The role of high-status voters and MP personal preferences on perceptual accuracy, with *whole electorate* as the reference constituency.

- **Figure C1:** The role of low-status voters and MP personal preferences on perceptual accuracy.
- **Table C5:** The role of high-status voters and MP personal preferences on perceptual accuracy, including undecided voters in public opinion measures.
- **Table C6:** The role of high-status voters and MP personal preferences on the gradation of accuracy.
- **Table C7:** The role of high-status voter and MP personal preferences on perceptual accuracy, with bootstrapped standard errors.
- **Table C8:** The role of high-status voter and MP personal preferences on perceptual accuracy, among large and small parties.
- **Table C9:** The marginal effects of white-collar voters disagreeing with the majority on perceptual accuracy, conditional on MP contacts with (a) blue-collar unions, and (b) business organizations. Complement to Figure 4.
- **Table C10:** The effects of different voter preferences on perceived policy support, conditional on MPs background. Complement to Figure 5.
- **Table C11:** The effects of white/blue-collar preferences on perceived support, conditional on constituents preference gap.

Appendix D - Study 2: Case selection

- Short description of the Swiss context and the opportunity provided by the instruments of direct democracy.

Appendix E - Study 2: Descriptives

- **Table E1:** Descriptive characteristics of the recruitment pool and study participants.
- **Table E2:** Covariate balance across treatment groups.
- **Figure E1:** Example of *Exposure* vignettes for self-determination initiative.
- **Figure E2:** Distributions of local-level support for the horned-cow and self-determination referendums.

Appendix F - Study 2: Additional analyses

- **Table F1:** The effects of exposure and self-awareness to social projection on perceptual accuracy. Complement to Figure 6.
- **Table F2:** The effects of self-awareness on the propensity of legislators to project their preferences on the electorate. Complement to Figure 7.
- **Table F3:** The effect of distance between survey completion and federal vote on perceptual accuracy.
- **Table F4:** Replication of main results among respondents who passed manipulation check.
- **Figure F1:** The effects of exposure and self-awareness to social projection on absolute misperceptions, by referendum.

Appendix G - Study 2: Informed consent and questionnaire

- Informed consent and questionnaire used in pre-referendum survey of Swiss local elected officials.

Appendix H - Hertel-Fernandez et al. (2019) extension

- **Table H1:** The effects of high-status voter preferences on perceptions of constituency preferences among US Congressional staffers. Extension of Hertel-Fernandez et al. (2019).

Appendix A - Study 1: The Swedish context

Study 1 is based on individual-level data from Swedish MPs. Sweden is a typical party-centered European system. Parties, as organizations, often play a significant role in providing the link between voters and representatives (Öhberg and Naurin 2016). Between 1985 and 2006, the period studied here, the political landscape was dominated by the Swedish Social Democratic party, winning the majority of votes in all seven elections with vote shares ranging from 35 to 45%. Public support for the remaining parties remained fairly stable throughout the two decades considered in the study. Figure A1 summarizes the vote shares received by the seven parties with at least one seat in the Swedish Riksdag during this period. Constitutionally, Sweden has influential parties organized in a parliamentary system with a low degree of separation of powers. Party cohesion is strong, but the relationship between candidates and voters is encouraged through a preferential vote system (Esaiasson and Holmberg 1996).

The Swedish Riksdag is composed by 349 members representing 29 multi-member districts. The districts vary in size, from Gotland (2 seats and roughly 44 thousand eligible voters) to Stockholm County (38 seats representing 892,592 voters, in 2014). Since 1985, the Swedish Parliamentary Study (RDU) regularly asks MPs to describe how important is promoting views they personally consider important, as part of their legislative work, *or* promote the views of their own constituency. Pooling the responses in all six waves of the survey, less than one fourth of MPs (22.0%) consider that behaving as a trustee is more important than behaving as a delegate. This statistic is likely to be inflated by social desirability bias, but still suggests that MPs recognize the value of accommodating voter preferences as part of their job. See Öhberg and Naurin (2016) for a similar conclusion. This is also consistent with research showing that voters consistently prefer their representatives to follow constituency preferences (Carman 2007; Converse and Pierce 1979; Dassonneville et al. 2020).

Figure A1: Electoral support for Swedish parties: 1985-2006.

Appendix B - Study 1: Descriptives

Appendix B describes a series of descriptive analyses from Study 1. Table B1 lists the policy issues asked in each wave of the mass surveys, along with average levels of public support. Table B2 describes the bivariate correlations between the different subconstituencies identified as high-status in the study. The correlations range from 0.08 to 0.35. Finally, Table B3 provides descriptive statistics of all the main variables included in the analyses.

Swedish MPs in the survey made inferences about the preferences of their “own party’s voters.” For the exposure hypothesis to apply to party constituencies, there should be sufficient variation in political resources among party supporters, and within each specific party. Figures B1-B5 support this assumption. First, Figure B1 compares the electorate as a whole and party supporters (with verified turnout) along the four dimensions used to measure high-status and low-status voters: income, education, social class, and place of residence. The distribution of political resources among party voters is very similar to the distribution in the electorate as a whole. Although party supporters tend to be slightly more affluent, the differences are residual. This result is not surprising given the high levels of turnout in Sweden, between 80 and 90% in the period studied. The same pattern holds within party. For instance, Figure B4 describes the income distributions within each of the seven parties included in Study 1. As expected, there are some differences across parties, with more affluent voters concentrated in more right-leaning parties. However, all parties include the full income range and party voters in a given year (with registered turnout) are only marginally more affluent than party sympathizers. The analysis reveals meaningful within-party heterogeneity in political resources.

Table B1: Policy issue questions concurrently asked in elite and mass surveys, and share of voters supporting each policy by year.

Policy issues	SNES	SOM	Survey Year					
			1985	1988	1994	1998	2002	2006
Reduce the public sector	✓	✓	41.6	38.5	32.6	26.6	26.8	29.2
Abolish the wage-earner funds	✓	-	55.5	-	-	-	-	-

Turkey should be granted membership	-	✓	-	-	-	-	-	12.3

Note: Entries are shares of supporters by policy issue and year (assuming a proportional distribution of undecided). SNES and SOM refer to the Swedish National Election Studies and the SOM Institute Survey, respectively. ✓s indicate that a given policy issue was asked in that survey. All policy items were also asked in the elite surveys.

Table B2: Correlations between measures of affluence in mass survey.

	White-collar	College degree	>85th income percentile	Urban
White-collar	-	0.28	0.35	0.15
College degree	-	-	0.21	0.08
>85th income percentile	-	-	-	0.19
Urban	-	-	-	-

Figure B1: Distribution of demographics among the electorate as a whole and party supporters.

Note: Each panel compares the demographic composition of the full sample of respondents in the mass surveys ($N = 29,190$), and the subset who reported voting for one of the parties included in the analysis, with verified turnout ($N = 24,075$).

Figure B2: Occupational social class distribution among party sympathizers (green) and party voters with verified turnout (orange).

Note: Each panel compares, for each party, the distribution of party sympathizers (green; $N = 27,653$) and party voters with verified turnout (orange; pooled $N = 24,705$), by occupational social class.

Figure B3: Education distribution among party sympathizers (green) and party voters with verified turnout (orange).

Note: Each panel compares, for each party, the distribution of party sympathizers (green; $N = 27,653$) and party voters with verified turnout (orange; pooled $N = 24,705$), by levels of education. Low = comprehensive school or lower; Medium = high school; High = college degree or higher.

Figure B4: Income distribution among party sympathizers (green) and party voters with verified turnout (orange).

Note: Each panel compares, for each party, the income distribution among party sympathizers (green; $N = 27,653$) and party voters with verified turnout (orange; pooled $N = 24,705$).

Figure B5: Distribution of place of residence among party sympathizers (green) and party voters with verified turnout (orange).

Note: Each panel compares, for each party, the distribution of party sympathizers (green; $N = 27,653$) and party voters with verified turnout (orange; pooled $N = 24,705$), by place of residence. Large cities = Stockholm, Gothenburg, and Malmö.

Appendix C - Study 1: Additional analyses

This section describes a series of robustness checks and sensitivity analyses complementing the main results of Study 1. Table C1 presents the full models used to build Figure 3 in the main text. Table C2 provides an alternative conceptualization of high-status constituents, based on gender. Consistent with the main findings, the analysis reveals that elite beliefs about their constituency are swayed by the preferences of male voters. On average, when male constituents disagree with the majority on a given issue, the probability that Swedish MPs correctly identify the majority opinion decreases by 7 percentage points.

Table C3 replicates the main analyses with fixed effects by individual MP (1,205 unique legislators). The results are robust to this stricter modelling strategy that account for any systematic differences across legislators. In Table C4, in turn, I replicate the main findings based on a different conceptualization of constituency: the electorate as a whole. This is possible since in 1985 (and only in this wave) the parliamentary survey asked MPs not only about the preferences of their own party voters (used in the main analyses), but also of the electorate as a whole. Besides the decrease in scope and statistical power, the same substantive results are obtained. These results suggest that the key findings reported in Study 1 do not seem to be contingent on the definition of constituency adopted.

Table C4 also allows for a naïve comparison between the effects of exposure and social projection for different reference constituencies. The coefficients for *High-Status* $\neq$ *Majority* in the electorate models (95% confidence interval = $[-0.01, -0.17]$) are indistinguishable from those estimated for party voters (Table C1; coefficients ranging from -0.04 and -0.12). At least in this specific comparison, inequalities in exposure have substantively the same effects for different representations of the public. One explanation for this result is that the demographics of Swedish party voters largely overlap with the demographics of the electorate as a whole (see Figure B1). In turn, social projection consistently affects perceptual accuracy, but the effects are larger for party voters (-0.38 ; s.e. = 0.01) than for the electorate as a whole (-0.32 ; s.e. = 0.02). This pattern is in line with prior research showing that individuals are more likely to project their preferences on groups perceived as more similar.

Figure C1, in turn, reveals that the effects of high-status disagreement does not replicate among low-status voters. When less privileged subconstituencies disagree with the majority in a given party, perceptual accuracy *does not* decrease. Tables C5, C6, C7, and C8 replicate the main analyses including a) undecided voters in the measure of public support, b) an alternative outcome variable that captures gradations of accuracy, c) bootstrapped clustered standard errors to account for uncertainty in public opinion estimates derived from the mass surveys, and d) distinguishing between large and small parties, respectively. These analyses mitigate concerns that the findings reported in the main text are contingent on the

measurement strategy adopted. Tables C9 and C10 provide supporting information to the mechanism tests for the exposure hypothesis, reported in the main text in Figures 4 and 5, respectively.

Finally, Table C11 provides an alternative modelling strategy to test the exposure hypothesis, modelling perceived support as a function of the interaction between high/low status voters, and the preference gap between subconstituencies. The results are consistent with the main findings and suggest that the predictive power of the preferences of less privileged subconstituencies (blue-collar voters) decreases as the gap in policy preferences between high- and low-status voters increases (model 2). The opposite is not true for the preferences of more privileged subconstituencies (model 1).

Figure C1: The role of low-status voters and MP personal preferences on perceptual accuracy.

Note: Dots are estimates from linear probability models with perceptual accuracy as the outcome variable. Horizontal lines represent 95% confidence intervals. The main predictors are listed on the *y*-axis. Each color represents a distinct model based on the operationalization of high-status voters.

Table C1: The role of high-status voters and MP personal preferences on perceptual accuracy. Complement to Figure 3.

Appendix D - Study 2: Case selection

Switzerland holds an average of 10 popular voters per year (Giger and Klüver 2016). There are three types of direct democratic instruments in the country: *mandatory referendums* for constitutional changes initiated by the Federal Assembly; *optional referendums* to vote on laws already accepted by the Federal Assembly; and *popular initiatives* where citizens can propose constitutional amendments, by collecting 100,00 signatures or more. The two issues explored in this study are popular initiatives. This study leverages referendum results to produce *accurate measures* of expressed voter preferences at the local (*gemeinde*) level.

It is worth elaborating on this opportunity. Previous work on perceptions of public opinion contrasted elite beliefs with constituency opinion based on nationally representative samples (e.g., Converse and Pierce 1986, Miller and Stokes 1963). However, by partitioning representative samples, the different sub-groups may no longer be representative. Recently, the combination of larger samples with poststratification techniques (Park et al. 2004) motivated new work on elite perceptions (Broockman and Skovron 2018; Hertel-Fernandez et al. 2019). However, this method still relies on important assumptions about the data (Buttice and Highton 2013), and sample sizes that are rare outside the United States. By relying on the actual behavior of voters on different referendums it is possible to have accurate measures of expressed preferences even in small administrative units.

Two other features of the Swiss context make it an interesting case to study elite misperceptions. First, the large number of popular votes gives Swiss representatives ample resources to develop accurate perceptions of voters. Second, Swiss municipalities are fairly small. In 2014, the average population was 3,545 inhabitants. Hence, the task of gauging public opinion is arguably easier than in larger and more diverse constituencies, leaving less room to improve elite perceptions.

Swiss municipalities are relatively small, with roughly half having less than 1,000 inhabitants. Despite their size, municipalities play an important role in the Swiss political system, being responsible for over 30% of public spending and having wide fiscal autonomy (Ladner 2005).

To collect data on elite perceptions of public support for the policy issues on the ballot, I fielded a survey with municipal representatives: members of the executive council. Municipal governments are governed by a local council and headed by a mayor, like most of their European counterparts (Norton 1991). The legislative side of Swiss local governments can either take the form of town meetings or city parliaments. But officials in this branch were not included in the study. Nearly two thirds of all councilors do not belong to a specific political party. Finally, like in the United States and in other European countries, in most Swiss municipalities local councilor is a part-time occupation.

Appendix E - Study 2: Descriptives

This section of the Appendix describes some relevant descriptive information from Study 2. Table E1 provides basic demographics of the sample of local officials who took part in the survey, and compares this sample with the larger pool of officials from which they were recruited ($N = 6,973$), representing nearly 60% of the population of Swiss local councilors. There are no statistically distinguishable differences across the samples on the observed characteristics. Figure E1 presents screenshots of the exposure vignette. Table E2, in turn, provides a series of covariate balance tests suggesting that the randomization worked properly on these relevant observables. Finally, Figure E2 plots the distribution of local support for the two initiatives included in the study. The distributions reveal considerable variation across municipalities.

Table E1: Descriptive characteristics of the recruitment pool and study participants.

	Pool	Sample
Female (%)	25.78	22.41
Age (years)	54.02	54.54
University degree or higher (%)	36.29	41.59
Experience in office (years)	7.9	8.0
In majority (%)	—	66.45
Hired by local administration (%)	30.90	29.98
Full time politician (%)	17.40	18.14
FDP member (%)	29.40	30.57
SVP member (%)	20.15	18.51
SP member (%)	12.96	15.87
Size of executive (N)	6.1	6.2
Population (N)	4463.0	4421.0
N	6,973	2,787

Note: The left column describes the pool of local officials surveyed in the 2017 National Survey of Members of Local Executives, representing $\approx 60\%$ of the population of Swiss local councilors. The right column describes the sample of officials recruited from this pool who took part in the current study.

Table E2: Covariate balance across treatment groups.

Covariates	Control	Exposure	Exposure & Self-Awareness	<i>p</i> -value
FDP member	0.29	0.30	0.32	0.34
SVP member	0.20	0.19	0.17	0.15
SP member	0.15	0.16	0.17	0.37
German language	0.70	0.72	0.71	0.85
Population	4502.76	4135.50	4620.25	0.82
% SVP support	34.55	34.45	33.89	0.28
% Foreign-born citizens	17.12	16.59	17.54	0.35
% SP+Green support	21.30	21.31	21.71	0.31
% Farmers	13.94	13.44	12.49	0.03
In Majority	0.67	0.67	0.65	0.50
Election expectations	3.37	3.42	3.41	0.49
Support for self-determination	0.34	0.33	0.33	0.88
Support for horned-cow	0.33	0.32	0.35	0.25
<i>Likelihood Ratio Test:</i>				
Exposure - Control	$\chi^2(24) = 18.2$		$Pr(> \chi^2) = 0.79$	
Exposure & Self-Awareness - Control	$\chi^2(24) = 16.8$		$Pr(> \chi^2) = 0.86$	
Exposure & Self-Awareness - Exposure	$\chi^2(22) = 15.3$		$Pr(> \chi^2) = 0.85$	

Note: Entries in the top panel are means of covariates across treatment conditions and *p*-values correspond to F tests of difference in means. The model fit of logistic regressions with treatment assignments as a function of all covariates was compared with the respective null model. The likelihood ratio tests described in the bottom panel do not reject the null models.

Figure E1: Example of *Exposure* vignettes for self-determination initiative.

Title: Self-Determination Initiative (Swiss Law over foreign judges)

Description: The initiative launched by the SVP/UDC seeks to solve conflicts between the Federal Constitution and the international treaties signed by Switzerland. The idea is that if a popular initiative supported by a majority is in conflict with a pre-existing international treaty, the constitution will have to prevail (subject to peremptory rules of international law, such as the prohibition of torture). Currently, in the event of conflicts between the constitution and an international treaty, a solution through democratic processes is favored. In most cases, these conflicts are solved through a law change subject to an optional referendum.

We will ask you to predict the share of voters in your municipality that will support the Self-Determination Initiative. However, because it is hard to anticipate the results of popular votes, **we will give you some tips in advance.**

(a) Policy description

Title: Self-Determination Initiative (Swiss Law over foreign judges)

When thinking about the preferences of voters, it often helps **considering the views of different groups in the constituency**. To help you in this process, think about the residents of [redacted] and give us your best guess to the following questions:

Your guess

In the 2015 federal elections, what share of voters in [redacted] voted for the SVP? %

What share of the population in [redacted] is foreigner? %

→

(b) Perceived electorate composition

Title: Self-Determination Initiative (Swiss Law over foreign judges)

To give you some reference points, here are your answers along with the most recent data from the Federal Statistical Office in your municipality and in Switzerland as a whole.

	Your guess	[redacted]*	Switzerland*
% SVP Supporters in 2015	28%	30.9%	29.4%
% Foreigners	11%	12.8%	24.6%

*Source: Federal Statistical Office

This information is intended to help you consider the preferences of the average voter in your municipality.

→

(c) Contrasting perceptions with statistical data

With this in mind, give us your expectation of **the share of voters in [redacted] that will SUPPORT the Self-Determination Initiative**. Please give us your best guess from 0% to 100%:

% of voters in [redacted] supporting the initiative

How confident are you in your prediction?

Not confident at all

Slightly confident

Moderately confident

Highly confident

→

(d) Measuring outcome

Note: Panel labels describe each step in the treatment, in alphabetical order. Panel (a) remained constant across treatment conditions (except for the last paragraph). Censored text refers to the municipality of the respondent.

Figure E2: Distributions of local-level support for the horned-cow and self-determination referendums.

Note: Lines represent density functions of the share of supporters in each municipality for each of the referendums.

Appendix F - Study 2: Additional analyses

This section presents a series of complementary results and sensitivity analyses regarding Study 2. Tables F1 and F2 complement Figures 6 and 7 in the main text. Table F3 test whether the time between survey completion and the referendums moderated perceptual accuracy, and the treatment effects. The analysis provides no conclusive results. In turn, Table F4 replicates the main results restricting the sample to respondents who passed the manipulation check. The effect sizes are consistently larger among local officials who passed the manipulation check. Finally, Figure F1 replicates the main analysis with an alternative pre-registered outcome variable: the absolute difference between the official's estimate and the referendum results. The results for each initiative separately are substantively the same. Only the coefficient of Electorate Composition in the pooled analysis is no longer reliable.

Table F1: The effects of exposure and self-awareness to social projection on perceptual accuracy. Complement to Figure 6.

	<i>Perceptual Accuracy</i>		
	Self-Determination	Horned-Cow	Pooled
	(1)	(2)	(3)
Exposure	0.06** (0.02)	0.03 (0.02)	0.05** (0.01)
Exposure & Self-Awareness	0.04* (0.02)	0.02 (0.02)	0.03* (0.01)
Horned-cow initiative	-	-	0.02 (0.01)
Constant	0.69** (0.01)	0.73** (0.01)	0.70** (0.01)
Observations	2,787	2,787	5,574
Adjusted R ²	0.003	0.000	0.002

Note: Entries are coefficients of linear probability models (SEs in parenthesis, and cluster-robust SEs in model 3) of the effect of providing information on the electorate composition and self-awareness on perceptual accuracy. *p<0.05; **p<0.01

Table F2: The effects of self-awareness on the propensity of legislators to project their preferences on the electorate. Complement to Figure 7.

	<i>Predicted support</i>		
	Self-Determination	Horned-Cow	Pooled
	(1)	(2)	(3)
Own support	3.10** (0.34)	4.54** (0.41)	3.77** (0.28)
Exposure & Self-Awareness	1.22 (1.13)	2.68* (1.36)	1.93* (0.92)
Own support × [Exposure & Self-Awareness]	−0.95* (0.48)	−1.17* (0.58)	−1.04** (0.40)
Horned-Cow Initiative	-	-	−7.33** (0.42)
Constant	37.63** (0.80)	26.88** (0.96)	36.01** (0.67)
Observations	1,803	1,797	3,600
Adjusted R ²	0.06	0.09	0.13

Note: Entries are OLS estimates of the effect of policy support on perceptions of public support, by treatment group (SEs in parenthesis, and cluster-robust SEs in model 3). Control group omitted to isolate the effect of the self-awareness intervention. *p<0.05; **p<0.01

Table F3: The effect of distance between survey completion and federal vote on perceptual accuracy.

	Self-Determination		Horned-Cow		Pooled	
	(1)	(2)	(3)	(4)	(5)	(6)
Distance to election (days)	−0.003 (0.002)	0.004 (0.004)	−0.004 (0.002)	−0.002 (0.004)	−0.003 (0.002)	0.001 (0.003)
Exposure	-	0.185 (0.094)	-	0.055 (0.092)	-	0.120 (0.064)
Distance × Exposure	-	−0.008 (0.006)	-	−0.002 (0.006)	-	−0.005 (0.004)
Exposure & Self-Awareness	-	0.197* (0.091)	-	0.045 (0.089)	-	0.121 (0.065)
Distance × Exposure & Self-Awareness	-	−0.011 (0.006)	-	−0.002 (0.006)	-	−0.006 (0.004)
Horned-cow initiative	-	-	-	-	0.019 (0.012)	0.019 (0.012)
Constant	0.766** (0.038)	0.632** (0.067)	0.800** (0.037)	0.765** (0.066)	0.773** (0.027)	0.689** (0.047)
Observations	2,787	2,787	2,787	2,787	5,574	5,574
Adjusted R ²	0.0001	0.003	0.001	−0.0002	0.001	0.002

Note: Entries are coefficients of linear probability models (SEs for models 1-4 and cluster-robust SEs for models 5-6) of the effect of distance between survey completion and election day, on perceptual accuracy. Models 1, 3, and 5 only include the measure of distance to referendum, while models 2, 4, and 6 interact this measure with the different treatments. *p<0.05; **p<0.01

Table F4: Replication of main results among respondents who passed manipulation check.

	<i>Perceived accuracy</i>		
	Self-Determination	Horned-Cow	Pooled
	(1)	(2)	(3)
Exposure	0.10** (0.03)	0.03 (0.03)	0.06** (0.02)
Exposure & Self-Awareness	0.06* (0.03)	0.02 (0.02)	0.04* (0.02)
Horned-cow initiative	-	-	0.02 (0.01)
Constant	0.68** (0.02)	0.73** (0.02)	0.70** (0.02)

Adjusted R ²	0.01	0.01	0.01

Note: Entries are coefficients of linear probability models (SEs for models 1-2 and cluster-robust SEs for model 3) of the effect of providing information on electorate composition and self-awareness on perceptual accuracy. *p<0.05; **p<0.01

Figure F1: The effects of exposure and self-awareness to social projection on absolute misperceptions, by referendum.

Note: Points are average treatment effects of exposure and exposure & self-awareness on absolute misperceptions (control group as reference point). Negative effects represent higher perceptual accuracy. Wider/Thinner horizontal lines are 95%/90% confidence interval from two-sample *t*-tests.

Appendix G - Study 2: Informed consent and questionnaire

Informed consent - first page of the questionnaire

We invite you to participate in a research study being conducted by investigators from the University of Geneva and Washington University in St. Louis. You are being asked to participate in this research study because you showed interest in taking part in a follow-up survey of the 2017 National Survey of Municipal Executive Members. The purpose of the study is to learn about your expectations for upcoming referendums. Approximately 2,000 people will take part in this study.

If you agree to participate, we would like you to ask about your opinion on different policy issues, and your expectations about the results of upcoming referendums. The survey is short and will not take more than 5 minutes. You are free to skip any questions that you prefer not to answer. If at any point you want to interrupt your participation, you can simply close the web page.

There are no known risks from being in this study, and you will not benefit personally. However, we hope that others may benefit in the future from what we learn as a result of this study. You will not have any costs for being in this research study. You will not be paid for being in this research study.

We will keep the information you provide confidential by not asking you any personal questions. However, federal regulatory agencies and Washington University, including the Washington University Institutional Review Board (a committee that reviews and approves research studies) and the Human Research Protection Office may inspect and copy records pertaining to this research. If we write a report about this study we will do so in such a way that you cannot be identified.

Your participation in this study is completely voluntary. You may choose not to take part at all. If you decide to participate in the study you may stop participating at any time. Any data that was collected as part of this study will remain as part of the study records and cannot be removed. If you decide not to take part in the study or if you stop participating at any time, you won't be penalized or lose any benefits for which you otherwise qualify. If you do not wish to participate in this study or want to end your participation in the study, return the survey without answering any of the questions. You will not be penalized or lose any benefits for which you otherwise qualify.

We encourage you to ask questions. If you have any questions about the research study itself or if you feel you have been harmed from being in the study, please contact: Professor Nathalie Giger (University of Geneva, nathalie.giger@unige.ch) or Miguel Pereira (Washington University, m.pereira@wustl.edu). If you have questions, concerns, or complaints about

your rights as a research participant, please contact the Human Research Protection Office at hrpo@wustl.edu. General information about being a research participant can be found on the Human Research Protection Office web site, <http://hrpo.wustl.edu>. To offer input about your experiences as a research participant or to speak to someone other than the research staff, call the Human Research Protection Office at the number above.

Thank you very much for your consideration of this research study.

Questionnaire

(Q1): We would like to start by asking you about your own position on a set of issues that will be subject to popular votes. Please indicate how much you Oppose or Support the following initiatives:

- Horned-Cow Initiative [The initiative aims to encourage farmers to raise cows and goats with horns through federal incentives.]
- Self-Determination Initiative [Requires that in cases of conflict between Swiss law and international law, the former prevails.]
- Legal basis for monitoring social insurance beneficiaries [To expand the surveillance capabilities of social insurance agencies investigating cases of suspicion involving social security beneficiaries.]

[Response options: Very opposed, Slightly opposed, Slightly supportive, Very supportive]

(Q2): In the last local election for your office, were there more than one candidate or party running?

- Yes
- No
- Not Applicable

[Q3-5: If Yes/No]

(Q3): In that election, what vote share did you or your party (if running in a list) receive? If you are not sure about the answer, just give us your best guess. You don't need to look it up.

- (Q4): Given your original expectations about the election, how did you feel about your results? The election results were: [Below my expectations, Slightly below my expectations, Just as I expected, Slightly above my expectations, Above my expectations]
- (Q5): Does your party or list currently hold a majority of seats in the executive? [Yes, No, Not Applicable]
- (Q6): On the 25th of November, Swiss citizens will be asked to vote on three federal referendums. On the next pages, we are interested in your expectations about the results of the referendums in your municipality: the share of voters in \$e://Field/City that you expect to support each initiative. Read carefully the description of each issue under consideration before giving your prediction.

[Q7-13: If Control = 1; otherwise, jump to Q14]

- (Q7): Title: Self-Determination Initiative (Swiss Law over foreign judges)
Description: The initiative launched by the SVP/UDC seeks to solve conflicts between the Federal Constitution and the international treaties signed by Switzerland. The idea is that if a popular initiative supported by a majority is in conflict with a pre-existing international treaty, the constitution will have to prevail (subject to peremptory rules of international law, such as the prohibition of torture). Currently, in the event of conflicts between the constitution and an international treaty, a solution through democratic processes is favored. In most cases, these conflicts are solved through a law change subject to an optional referendum.
- (Q8): It is always hard to anticipate the results of popular votes, but we would like to ask you to predict the share of voters in \$e://Field/City that will SUPPORT the Self-Determination Initiative.

Please give us your best guess from 0% to 100%: [0-100%]

- (Q9): How confident are you in your prediction? [Not confident at all, Slightly confident, Moderately confident, Highly confident]
- (Q10): On the next page, you will be asked to consider a different initiative that will be voted on the 25th of November.
- (Q11): Title: For the dignity of livestock (Horned-Cow Initiative)
Description: Launched by the interest group “Hornkuh”, this initiative aims to encourage farmers to raise cows and goats with horns. Today, 3 out of 4 cows are dehorned.

Dehorning facilitates free-range cattle growing because it reduces the risk of injury. However, dehorning is a controversial practice. Since raising horned animals entails higher costs, the authors of the initiative would like the Confederation to support livestock producers.

(Q12): It is always hard to anticipate the results of popular votes, but we would like to ask you to predict the share of voters in \$e://Field/City that will SUPPORT the Horned-Cow Initiative.

Please give us your best guess from 0% to 100%: [0-100%]

(Q13): How confident are you in your prediction? [Not confident at all, Slightly confident, Moderately confident, Highly confident]

[Q14-26: If Exposure = 1 OR Exposure+Self-Awareness = 1; otherwise, jump to Q27;
randomize order of issue]

(Q14): Title: For the dignity of livestock (Horned-Cow Initiative)

Description: Launched by the interest group “Hornkuh”, this initiative aims to encourage farmers to raise cows and goats with horns. Today, 3 out of 4 cows are dehorned. Dehorning facilitates free-range cattle growing because it reduces the risk of injury. However, dehorning is a controversial practice. Since raising horned animals entails higher costs, the authors of the initiative would like the Confederation to support livestock producers.

We will ask you to predict the share of voters in your municipality that will support the Horned-Cow Initiative. However, because it is hard to anticipate the results of popular votes, we will give you some tips in advance.

(Q15): Title: For the dignity of livestock (Horned-Cow Initiative)

When thinking about the preferences of voters, it often helps considering the views of different groups in the constituency. To help you in this process, think about the residents of \$e://Field/City and give us your best guess to the following questions:

- What share of the workers in \$e://Field/City works in the primary sector (including agriculture, forestry, or fishing)? [0-100%]

- In the 2015 federal elections, what was the combined share of votes received by the SP and the GPS in \$e://Field/City? [0-100%]

(Q16): To give you some reference points, here are your answers along with the most recent data from the Federal Statistical Office in your municipality and in Switzerland as a whole.

	Your guess	\$e://Field/City*	Switzerland*
% Workers in primary sector	from Q15	\$e://Field/Farmers	3.2%
% SP and GPS supporters in 2015	from Q15	\$e://Field/Left	25.9%

* Source: Federal Statistical Office

[Q17: If Exposure+Self-Awareness = 1, otherwise jump to Q18]

(Q17): Finally, one last tip. Decades of research show that people tend to project their own preferences on others. Without noticing, we often overestimate approval for issues we support, while underestimating approval for issues we oppose. Try to take this into account when making your prediction.

(Q18): With this in mind, give us your expectation of the share of voters in \$e://Field/City that will SUPPORT the Horned-Cow Initiative. Please give us your best guess from 0% to 100%: [0-100%]

(Q19): How confident are you in your prediction? [Not confident at all, Slightly confident, Moderately confident, Highly confident]

(Q20): On the next page, you will be asked to consider a different initiative that will be voted on the 25th of November.

(Q21): Title: Self-Determination Initiative (Swiss Law over foreign judges)

Description: The initiative launched by the SVP/UDC seeks to solve conflicts between the Federal Constitution and the international treaties signed by Switzerland. The idea is that if a popular initiative supported by a majority is in conflict with a pre-existing international treaty, the constitution will have to prevail (subject to peremptory rules of international law, such as the prohibition of torture). Currently, in the event of conflicts between the constitution and an international treaty, a solution through democratic processes is favored. In most cases, these conflicts are solved

through a law change subject to an optional referendum.

We will ask you to predict the share of voters in your municipality that will support the Self-Determination Initiative. However, because it is hard to anticipate the results of popular votes, we will give you some tips in advance.

(Q22): Title: Self-Determination Initiative (Swiss Law over foreign judges)

When thinking about the preferences of voters, it often helps considering the views of different groups in the constituency. To help you in this process, think about the residents of \$e://Field/City and give us your best guess to the following questions:

- In the 2015 federal elections, what share of voters in \$e://Field/City voted for the SVP? [0-100%]
- What share of the population in \$e://Field/City is foreigner? [0-100%]

(Q23): To give you some reference points, here are your answers along with the most recent data from the Federal Statistical Office in your municipality and in Switzerland as a whole.

	Your guess	\$e://Field/City*	Switzerland*
% SVP Supporters in 2015	from Q22	\$e://Field/SVP	29.4%
% Foreigners	from Q22	\$e://Field/Foreigners	24.6%

* Source: Federal Statistical Office

[Q24: If Exposure+Self-Awareness = 1, otherwise jump to Q25]

(Q24): Finally, one last tip. Decades of research show that people tend to project their own preferences on others. Without noticing, we often overestimate approval for issues we support, while underestimating approval for issues we oppose. Try to take this into account when making your prediction.

(Q25): With this in mind, give us your expectation of the share of voters in \$e://Field/City that will SUPPORT the Self-Determination Initiative. Please give us your best guess from 0% to 100%: [0-100%]

(Q26): How confident are you in your prediction? [Not confident at all, Slightly confident, Moderately confident, Highly confident]

(Q27): In the prediction tasks above, which tips were you provided?

- No tips
- Information about the electorate
- Information about the electorate and a suggestion to avoid projecting my own preferences
- The results from an old referendum

[Q28: If Control = 1, otherwise jump to Q29]

(Q28): This is your final screen. We know that survey questions sometimes don't allow one to tell the full story. We would welcome any feedback or suggestions you have on the survey in the box below: [open answer]

(Q29): Would you like to be contacted with any reports we create based on this survey? We believe this can make your experience in the study more interesting. [Yes/No]

That concludes the survey. Thank you for your time!

Appendix H - Hertel-Fernandez et al. (2019) extension

A potential concern with Study 1 is that Swedish MPs were asked to estimate the perceptions of policy preferences among party voters and not the electorate as a whole. It is reassuring to find substantively the same patterns among the electorate as a whole in the first wave of the Riksdag panel (Table C4; see also Study 2). To further explore the sensitivity of the arguments to different conceptualizations of constituency, in this section I describe an out-of-sample test of the exposure and social projection hypotheses. To do so, I replicate and extend the analyses in Hertel-Fernandez et al. (2019). In the original study, the authors surveyed Congressional staffers in the United States about their perceptions of policy preferences nationwide, and contrasted these beliefs with public opinion data from the Cooperative Congressional Election Study (CCES). Legislative staffers are a key source of information to politicians, acting as the “bridge between elected officials, the public, and interest groups” (Hertel-Fernandez et al. 2019; 1). As the original study articulates, distortions in perceptions of public opinion among staffers are likely reflected on legislators.

I extended the original analyses distinguishing between the preferences of high-status voters and the majority following as close as possible the operationalization of the independent variables in Study 1. High-status voters are measured as (1) white-collar voters, (2) voters with a college degree or higher, and (3) voters in the top 15th income percentile. The outcome variable in all models is the respondents’ estimate of the share of constituents supporting a given policy.

To test the exposure hypothesis, the main predictor is difference between the share of high-status voters supporting the policy and the majority opinion (*High-Status – Majority*). If officials are swayed by the preferences of high-status voters, there should be a positive relationship between this preference differential and perceptions of public opinion. The models also include an indicator for whether the respondent (1) supports or (0) opposes each specific policy included in Hertel-Fernandez et al.. Consistent with the social projection hypothesis, I expect a positive relationship between policy support and perceptions of public opinion. All models include fixed effects by party and clustered standard errors by individual respondent.

The results reported in Table H1 are consistent with the findings in Study 1. Models 1, 3, and 5 in each table report simple regressions with the measure of preference differential as the predictor, while Models 2, 4, and 6 report multiple regressions including the measure of personal preferences and fixed effects by party. The positive coefficients for *High-Status – Majority* suggest that when high-status voters deviate from the majority opinion, perceptions of public opinion tend to follow the position of the more privileged subconstituency. The effects are meaningful. Using model 2 as an example, the coefficient for *High-Status –*

Majority (1.96; s.e. = 0.22) means that when the share of high-collar voters supporting a given policy is 5 points higher than the electorate as a whole, perceptions of public support the same policy are, on average, 9.8 percentage points higher. This pattern is consistent with the exposure hypothesis. Finally, the analyses also support the social projection hypothesis. On average, perceptions of the share of public support for a given policy are 12.5-13.1 percentage points higher among respondents who support the policy. Together, the results provide additional evidence for the two main theoretical predictions in the paper.

Table H1: The effects of high-status voter preferences on perceptions of constituency preferences among US Congressional staffers. Extension of Hertel-Fernandez et al. (2019).

	Social Class		Education		Income	
	(1)	(2)	(3)	(4)	(5)	(6)
High-Status – Majority	2.56** (0.23)	1.94** (0.22)	2.03** (0.19)	1.57** (0.17)	1.63** (0.15)	1.17** (0.15)
Supports policy		13.13** (1.89)		12.48** (1.85)		13.59** (1.92)
Republican		–0.33 (1.15)		–0.35 (1.17)		–0.61 (1.17)
Constant	58.50** (0.88)	48.57** (1.56)	61.70** (1.08)	50.19** (1.85)	57.66** (0.84)	46.76** (1.55)
Observations	368	367	368	367	368	367
Adjusted R ²	0.23	0.35	0.26	0.37	0.21	0.34

Entries are model coefficients of OLS models (cluster-robust standard errors in parenthesis) with perceived public support as the outcome variable. Column headers describe the conceptualization of high-status voters in each model: white-collar voters (columns 1, 2), voters with college degree (columns 3, 4), and voters in top 15% income percentile. **p < 0.01; *p < 0.05
