ABSTRACT

The MolMod database is presented, which is openly accessible at <http://molmod.boltzmann-zuse.de> and contains intermolecular force fields for over 150 pure fluids at present. It was developed and is maintained by the Boltzmann-Zuse Society for Computational Molecular Engineering (BZS). The set of molecular models in the MolMod database provides a coherent framework for molecular simulations of fluids. The molecular models in the MolMod database consist of Lennard-Jones interaction sites, point charges, and point dipoles and quadrupoles, which can be equivalently represented by multiple point charges. The force fields can be exported as input files for the simulation programmes *ms2* and *Is1* mardyn, GROMACS, and LAMMPS. To characterise the semantics associated with the numerical database content, a force field nomenclature is introduced that can also be used in other contexts in materials modelling at the atomistic and mesoscopic levels. The models of the pure substances that are included in the database were generally optimised such as to yield good representations of experimental data of the vapour–liquid equilibrium with a focus on the vapour pressure and the saturated liquid density. In many cases, the models also yield good predictions of caloric, transport, and interfacial properties of the pure fluids. For all models, references to the original works in which they were developed are provided. The models can be used straightforwardly for predictions of properties of fluid mixtures using established combination rules. Input errors are a major source of errors in simulations. The MolMod database contributes to reducing such errors.

KEYWORDS

Molecular models; force field database; thermophysical properties; molecular dynamics; Monte Carlo

1. Introduction

Reliable information on thermophysical properties is of fundamental importance for the development and optimisation of processes in chemical engineering, but also in many other fields, such as energy conversion and storage. With the increasing availability of computational resources, simulation techniques are today an attractive alternative to classical experiments in laboratories to obtain accurate thermophysical properties [1–3]. Compared to laboratory experiments, computer experiments have the advantage that problematic substances (toxic, flammable, explosive, etc.) and extreme conditions can be studied without any problems. Computer experiments, like molecular dynamics (MD) and Monte Carlo (MC), have therefore become an accepted complement and sometimes even substitute to traditional experimental work. Therefore, many scientific journals that were afore focussed on reporting experimental data on thermophysical properties have started recently to accept and also call for corresponding molecular simulation data [4]. Especially phase equilibria, transport, and interfacial properties of pure fluids and fluid mixtures are of special interest in chemical engineering and also in many other fields. Knowledge of these thermophysical properties is often required for a wide range of temperature and pressure and with a high accuracy. The accuracy of thermophysical property data obtained by molecular simulation, in the sense that the simulation shall reproduce properties of real substances, depends mainly on the applied force field. The development of suitable force fields is therefore

of prime importance for the success of molecular methods in materials modelling. Moreover, it is not sufficient that good force fields are developed. They must also be made available to potential users in a way that they can be handled easily in the simulation package with which the user wants to carry out his work. This is of special importance, as input errors are known to be one of the major sources of simulation errors[5]. The present work addresses this challenge.

Generalised force fields, such as CHARMM [6–9], AMBER [10–12], or GROMOS [13, 14], are mainly used for biological systems, and focus therefore on aqueous systems at near-ambient conditions. Such generalised force fields mostly do not satisfy the accuracy that is required in chemical engineering for data on phase equilibrium, transport, and interfacial properties. Force fields that are particularly aiming at an accurate description of phase equilibria are for example OPLS [15–17], TraPPE [18], and OPPE [19–21]. These are transferable force fields which means that the interaction parameters of chemical groups or atoms can be transferred among substance families, like alkanes.

The molecular models of the pure substances in the MolMod database [22] were tailored to describe thermophysical properties of that substance. Only fluid properties are considered. The interaction parameters of a molecular species are only valid for that very substance, i.e. no extrapolation to other substances is intended. The advantage of this individual parametrisation lies in the high accuracy of each model which can be achieved. Furthermore, it is known that using

such models, extrapolations to other thermophysical properties and other conditions than those that were used in the parametrisation are often successful [23–26]. The models can also be applied for studying fluid mixtures using well-established combination rules [27]. The force fields in the MolMod database were developed under the auspices of the Boltzmann-Zuse Society of Computational Molecular Engineering (BZS) as described in more than 30 original peer-reviewed publications. The molecular models were parametrised in a consistent way with respect to vapour–liquid equilibrium data, which is therefore described very well. Other pure component properties, such as homogeneous pVT data, caloric properties, speed of sound, and interfacial properties, predicted from these models were found to be in good agreement with experimental data where available [25, 28–33]. The MolMod database currently consists of molecular models for approximately 150 pure substances of mainly moderately sized molecules that are modelled as rigid bodies. Also multiple models for ions are included. The molecular models in the MolMod database consist of Lennard-Jones interaction sites, point charges, and point dipoles and quadrupoles.

The models can also be combined to describe mixtures. Usually, the Lorentz-Berthelot combination rules are found to yield acceptable predictions of the behaviour of binary and multicomponent mixtures. However, the accuracy is then often below that which is achieved for the pure substances. To obtain a similar accuracy also for mixtures, it is often sufficient to adjust a single state-independent binary parameter in the Berthelot combination rule for the dispersive cross-interaction [27, 34].

The core of the MolMod database is a download feature for several molecular simulation codes. The codes that are supported in the present version are LAMMPS [35], GROMACS [36], *ms2* [37], and *ls1 mardyn* [38]. Databases that provide input files for molecular interactions and generalised force fields have already been introduced in the fields of microbiology and chemistry [8, 9, 12, 39–42], but to the best of our knowledge not for individually parametrised highly accurate molecular force fields, focussing on the description of thermophysical properties of fluids.

2. MolMod database

The MolMod database <http://molmod.boltzmann-zuse.de> (Web frontend cf. Figure 1) provides a range of search functionalities, e.g. for substances, CAS numbers, model classes, etc. Each molecular model has an individual page, which contains the full specification of the molecular model and the download links for the input files. Also, each molecular model is hyperlinked to the original publication. The database contains a comprehensive nomenclature section that describes the specifications in the input files for all supported simulation programmes to facilitate the simulators integrating the force fields in their simulation workflows. Known misprints in publications are clearly emphasised in the database.

All force fields in the MolMod database are currently rigid single- or multi-site models, consisting of Lennard-Jones 12-6 interaction sites, point charges, point dipoles, and point quadrupoles. All supported interaction potentials are pairwise additive.

In all models, the repulsion and dispersion between two particles i and j at a distance r_{ij} are described by the standard Lennard-Jones 12-6 potential

$$u_{ij}^{\text{LJ}}(r) = 4\varepsilon \left[\left(\frac{\sigma}{r_{ij}} \right)^{12} - \left(\frac{\sigma}{r_{ij}} \right)^6 \right], \quad (1)$$

where ε is the dispersion energy and σ the size parameter of an interaction site. The interaction between two different Lennard-Jones sites is described by the Lorentz-Berthelot combination rules [43, 44].

The electrostatic interactions are modelled by point charges, point dipoles, and point quadrupoles. The latter two describe the electrostatic field of two and four point charges of the same magnitude, respectively. The advantage of higher order polarities in molecular simulations lies in a reduction of computational effort of up to 60% compared to a corresponding arrangement of point charges [45]. It has also been claimed that multipoles give a better description of electrostatic interactions [46].

The electrostatic potential between two point charges q_i and q_j is given by Coulomb's law

$$u_{ij}^{\text{ee}}(r_{ij}) = \frac{1}{4\pi\epsilon_0} \frac{q_i q_j}{r_{ij}}, \quad (2)$$

where q_i is the magnitude of the charge i and r_{ij} the distance between two point charges i and j .

A point dipole describes the electrostatic field of two point charges with equal magnitude, but opposite sign at a mutual distance $a \rightarrow 0$. Its dipole moment magnitude is defined by $\mu = qa$. The electrostatic potential between two point dipoles with the moments μ_i and μ_j at a distance r_{ij} is given by [47–49]

$$\begin{aligned} u_{ij}^{\text{dd}}(r_{ij}, \theta_i, \theta_j, \phi_{ij}) \\ = \frac{1}{4\pi\epsilon_0} \frac{\mu_i \mu_j}{r_{ij}^3} \left[(\sin(\theta_i) \sin(\theta_j) \cos(\phi_{ij}) - 2 \cos(\theta_i) \cos(\theta_j)) \right], \end{aligned} \quad (3)$$

where the angles θ_i , θ_j and ϕ_{ij} indicate the relative angular orientation of the two point dipoles with the former indicating the angle between the dipole direction and the distance vector of the two interacting dipoles and ϕ_{ij} being the azimuthal angle of the two dipole directions.

A linear point quadrupole describes the electrostatic field induced either by two collinear point dipoles with the same moment, but opposite orientation at a distance $a \rightarrow 0$ or three point charges, e.g. $(q, -2q, q)$. The quadrupole magnitude Q is defined as $Q = 2qd^2$, where q is the characteristic magnitude of the three charges, and d is the distance between each of the outer charges (magnitude q) and the $-2q$ charges in the centre. The interaction potential is given by [47–49]

$$\begin{aligned} u_{ij}^{\text{qq}}(r_{ij}, \theta_i, \theta_j, \phi_{ij}) \\ = \frac{1}{4\pi\epsilon_0} \frac{3}{4} \frac{Q_i Q_j}{r_{ij}^5} \left[1 - 5((\cos \theta_i)^2 + (\cos \theta_j)^2) \right. \\ \left. - 15(\cos \theta_i)^2 (\cos \theta_j)^2 \right. \\ \left. + 2(\sin \theta_i \sin \theta_j \cos \phi_{ij} - 4 \cos \theta_i \cos \theta_j)^2 \right], \end{aligned} \quad (4)$$

Figure 1. (Colour online) Graphical design of the MolMod homepage: <http://molmod.boltzmann-zuse.de> (colour online).

where the angles θ_i , θ_j , and ϕ_{ij} indicate the relative angular orientation of the two point quadrupoles. The interaction potentials between unlike electrostatic site types can also be derived from the laws of electrostatics straightforwardly.

For a detailed derivation of these equations, cf. Gray and Gubbins [48].

For mixtures of fluids from the MolMod database, the modified Lorentz-Berthelot combination rules proved to give

an accurate description of fluid mixtures [27, 34, 50]

$$\sigma_{ij} = \eta \frac{\sigma_i + \sigma_j}{2}, \quad (5)$$

$$\varepsilon_{ij} = \xi \sqrt{\varepsilon_i \varepsilon_j}, \quad (6)$$

where ξ and η are state-independent adjustable binary interaction parameters to explicitly consider the non-ideality of the respective mixture. Binary interaction parameters ξ adjusted to binary vapour-liquid equilibrium data [34, 51] are available for approximately 400 mixtures of molecular models from the MolMod database. It could be shown that the original Lorentz combination rule, i.e. $\eta = 1$, is a good approximation in most cases [27]. Using the input files provided by the MolMod database for the simulation of mixtures with the programmes *ms2* and *ls1*, mardyn is straightforward [37, 38] as their syntax only requires the additional specification of the mole fractions and eventually the binary interaction parameters for mixtures. However, the numeric values for the binary parameters ξ are currently not provided by the database.

The parametrisation of molecular models that are part of the MolMod database was usually carried out in two steps: The geometry and charge distribution of multi-site models was obtained from quantum chemical calculations. The remaining intermolecular interactions were then optimised to vapour-liquid equilibrium data, i.e. saturated liquid density, vapour pressure, and enthalpy of vaporisation. Also, automated simulation and optimisation workflows have been employed, operating in the parameter space locally [52, 53] as well as globally [54], which leads to a significant reduction of the effort. Multicriteria optimisation based on the analysis of a Pareto set has also been employed for the parametrisation lately [55–57] to explicitly consider conflicting objectives. The agreement with experimental data is typically found to be within 4% for the vapour pressure, 0.5% for the saturated liquid density, and 3% for the enthalpy of vaporisation. Predicted thermophysical properties that were not considered during the parametrisation agree with experimental data approximately within 10% for transport properties, and 20% for surface tension data. In some cases, the deviations of the model behaviour from the available experimental data are smaller than the experimental uncertainty for a wide variety of thermophysical properties [26]. Some of the molecular models have also been employed to complement experimental data sets for the development of high-accuracy equations of state [30, 58] for engineering applications.

Table 1 summarises the molecular substances that are currently available in the MolMod database, sorted by the number of carbon atoms. The database contains molecular models of different substance classes, e.g. organic substances, noble gases, and chlorofluorocarbons. Organic substances in the database are from different chemical families, like alkanes, alkenes, alcohols, aromatics, amines, ketones, nitriles, acids, etc. Molecular models for numerous substances of fundamental importance for the chemical industry are covered, such as methanol, ethanol, formic acid, ammonia, formaldehyde, hydrogen cyanide, acetonitrile, ethylene oxide, toluene, ethylene glycol, acetone, etc. A second focus of the MolMod database comprises

important refrigerants, of which it contains approximately 30, such as R134a, R22, R12, R227ea. The MolMod database also contains molecular models for substances that are gases at ambient conditions and are for example important in environmental science, such as O₂, N₂, CO, CO₂, N₂O, H₂, H₂O, SO₂, or Ar. Also some models for ions are available in the MolMod database [77–79].

3. Available input formats

Questions regarding the molecular topology and the interaction specifications in a certain simulation programme are among the most common ones in the mailing lists, for example for LAMMPS [35] and GROMACS [36]. The ‘by hand’ implementation of force fields is a sensitive task [5] due to questions like angle definitions, units, and geometry specifications, etc. Ready-to-use and validated force field input files are – where available – a welcome support to simulators. The MolMod database currently provides input files for the simulation programmes LAMMPS [35], GROMACS [36], *ms2* [37], and *ls1* mardyn [38]. Since these molecular simulation codes are based on different approaches to realise for example multipole interactions, the geometry definition or the rigidity constraint of molecules, on the fly conversion routines were implemented in the database.

Since most simulation programmes cannot handle point dipoles or point quadrupoles explicitly, they are converted on the fly into the corresponding configuration of point charges, i.e. $(+q, -q)$ for dipoles and $(+q, -2q, +q)$ for quadrupoles. Despite the fact that point multipoles are computationally much cheaper than a corresponding configuration of point charges, both are physically equivalent [80]. As there is one degree of freedom for replacing point dipoles and point quadrupoles by point charges, a rational choice for one parameter – either the elongation or the magnitude of the point charge – has to be made. This problem was addressed in the work of Engin et al. [80] for the molecular model class of 2CLJD and 2CLJQ. Engin et al. [80] could show that setting the distance a or d between the two point charges to $\sigma/20$, where σ is the size parameter of the Lennard-Jones site, leads to excellent agreement between a multipole and the corresponding configuration of point charges. The magnitude of the two point charges q is then straightforwardly computed as

$$q = \frac{\mu}{a} = \frac{20\mu}{\sigma}, \quad (7)$$

for dipoles and

$$q = \frac{Q}{2d^2} = \frac{200Q}{\sigma^2}, \quad (8)$$

for quadrupoles. This method was extended in the MolMod database to arbitrary molecular structures by calculating the parameter a or d by means of the Lennard-Jones interaction site closest to the point dipole according to the Euclidean norm. Also, the geometry of the molecular models is adapted to the demands of each simulation programme, as some require internal Z-matrix coordinates and others xyz-coordinates. Particular care was also taken regarding the units of each numeric value.

Table 1. List of molecular force fields currently available in the molMod database.

Substance	CAS No.	Name	Reference
Ar	7440-37-1	Argon	[59, 60]
Br ₂	7726-95-6	Bromine	[56, 59]
Cl ₂	7782-50-5	Chlorine	[59]
F ₂	7782-41-4	Fluorine	[56, 59]
H ₂	1333-74-0	Hydrogen	[61]
H ₂ O	7732-18-5	Water	[62]
H ₄ N ₂	302-01-2	Hydrazine	[63]
HCl	7647-01-0	Hydrochloric acid	[23]
I ₂	7553-56-2	Iodine	[59]
Kr	7439-90-9	Krypton	[59, 60]
N ₂	7727-37-9	Nitrogen	[56, 59]
N ₂ O	10024-97-2	Nitrous oxide	[57]
Ne	7440-01-9	Neon	[59]
NH ₃	7664-41-7	Ammonia	[28]
O ₂	7782-44-7	Oxygen	[56, 59]
SF ₆	2551-62-4	Sulphur hexafluoride	[59]
SO ₂	7446-09-5	Sulphur dioxide	[64]
Xe	7440-63-3	Xenon	[59, 60]
CB ₂ F ₂	75-61-6	Dibromodifluoromethane	[65]
CBrCl ₃	75-62-7	Bromotrichloromethane	[65]
CBrClF ₂	353-59-3	Bromochlorodifluoromethane	[65]
CBrF ₃ (R13B1)	75-63-8	Bromotrifluoromethane	[65]
CCl ₂ O	75-44-5	Phosgene	[23]
CCl ₄	56-23-5	Carbon tetrachloride	[29, 59]
CClN	506-77-4	Cyanogen chloride	[66]
CF ₂ Cl ₂ (R12)	75-71-8	Dichlorodifluoromethane	[65]
CF ₃ Cl (R13)	75-72-9	Chlorotrifluoromethane	[65]
CF ₄	75-73-0	Tetrafluoromethane	[59]
CFCl ₃ (R11)	75-69-4	Trichloromonofluoromethane	[65]
CH ₂ Br ₂	74-95-3	Dibromomethane	[65]

C ₈ H ₂₄ O ₄ Si ₄	556-67-2	Octamethylcyclotetrasiloxane	[76]

Each molecular force field consists of a single and unique set of parameters that is converted on demand into the desired input file format. All data are stored in the database using SQL (structured query language) to ensure flexibility and robustness with the data handling. All types of molecular force fields in the MolMod database were validated for the supported simulation programmes.

4. Nomenclature

A comprehensive description of the nomenclature for all supported input files is given to facilitate the integration of the

force field input files into the workflow of a simulator. The input files for the different simulation programmes that are provided by the MolMod database contain basically only numbers in the specified formats, sometimes in combination with keywords. As such they are ready-to-use. This is sufficient for standard applications of the corresponding simulation programmes. But numbers that carry no semantics are insufficient for anything that goes beyond plug and play. Therefore, the MolMod database contains a comprehensive description of the content of the input files for all supported simulation programmes and the force field definition in the MolMod web frontend. This description of meaning of the provided data enables using the data also in non-standard applications and ensures that the contents become genuinely interoperable with data and metadata from other sources, for example for the virtual materials market place (VIMMP) where data pertaining to a variety of modelling paradigms need to be processed and made accessible to end users in a coherent way [81].

Appropriate semantic assets were defined for each entity of the database and eventually for their relations. The database was then complemented by an according nomenclature, i.e. a conceptual model of the employed entities in a descriptive form that is to be processed by humans, not by machines. This nomenclature, which is available on the MolMod web frontend, builds on – and is compatible with – the Review of Materials Modelling (RoMM) by de Baas [82]. It defines the sense in which the terms associated with the database entries are meant to be used, including, but not limited to

- geometry definitions (*xyz*-coordinates, Z-matrix, angle and dihedral definitions, etc.)
- definition of multipole moments and equivalent point charge configurations
- employed unit systems.

5. Summary and future work

In the present work, the MolMod database is introduced. It is an open accessible database of molecular models for fluids and contains models of about 150 pure substances at present. The models were parametrised in previous work such as to yield a good description of experimental data of the vapour–liquid equilibrium of the studied fluid. Many of the models have also been tested with respect to caloric, transport, and interfacial properties and the predictions were often found to be in good agreement with experimental data. This makes the models provided in the MolMod database interesting for applications in chemical engineering and many other fields of science and technology.

The MolMod database provides ready-to-use input files for different common molecular simulation packages. This reduces the risk of input errors in the simulations. But the MolMod database also contains additional information: References to the original work in which the models were developed are given as well as known misprints clearly pointed out. Furthermore, the MolMod database also provides detailed descriptions of all entities in the input files that are available from the database.

The MolMod database was developed and is maintained by the Boltzmann Zuse Society of Computational Molecular

Engineering (BZS). The models that are presently included were developed and tested by BZS members, but the MolMod database is open for contributions from other groups. Any tailor-made molecular model of a fluid that fits into the scope of the MolMod database may be included, provided that its development and testing have been described in a peer-reviewed scientific paper and that a sufficiently accurate description of relevant thermophysical data is achieved. Suggestions to include new models can be filed via the MolMod homepage.

In its present version, the MolMod database only contains models of simple fluids without internal degrees of freedom. An extension to larger molecules that require the consideration of internal degrees of freedom is interesting. The same holds for an extension to the Mie potential instead of the Lennard-Jones 12-6 potential. Future work will also aim at providing input files for other molecular simulation programmes than GROMACS, LAMMPS, *ms2*, *ls1* mardyn, that are already served.

Ongoing and future developments will also advance the semantic technology that underlies to the MolMod database to include (or attach to) machine-readable assets, e.g. by rigorously relating the present nomenclature, that categorises and describes atomistic and mesoscopic materials models, to the MODA Workow Graph Language [83], ontologies such as the European Materials Modelling Ontology [84], and the metadata model EngMeta [85]. This will facilitate integrating the MolMod database as a component into future development work towards open translation environments, i.e. platforms that generate materials modelling workflows that are tailored to the needs of the end user, and virtual marketplace platforms where materials modelling services and data access can be traded. Various approaches for providing such environments have so far been envisioned; cf. de Baas [82] for a detailed discussion of the position that semantic assets for molecular modelling and simulation, model repositories, and repositories for simulation data and metadata may occupy within a coherent approach to materials modelling interoperability and standardisation.

Acknowledgments

We gratefully appreciate running test simulations for the validation of the *ls1* mardyn, GROMACS and LAMMPS input files by Matthias Heinen, Edder J. Garcia and Angelo Damone, respectively. The simulations for the parametrisation of the force fields were carried out on the HazelHen at High Performance Computing Center Stuttgart (HLRS) under the grant MMHBF2 as well as on the SuperMUC at Leibniz Supercomputing Centre (LRZ) Garching under the grant SPARLAMPE (pr48te). The present research was conducted under the auspices of the Boltzmann-Zuse Society of Computational Molecular Engineering (BZS).

Disclosure statement

No potential conflict of interest was reported by the authors.

Funding

The authors gratefully acknowledge funding of the present work by the Reinhart Koselleck programme of the Deutsche Forschungsgemeinschaft (DFG), and the TaLPas project by the German Federal Ministry of Education and Research (Bundesministerium für Bildung und Forschung) (BMBF). The co-authors Simon Stephan and Hans Hasse acknowledge funding by the European Union's "Horizon 2020 research and innovation

programme" (grant agreement No. 694807 – ENRICO) and the co-author Martin Horsch by (grant agreement No. 760907 – VIMMP).
