This work received financial support from CONICYT (National Council for Scientific and Technological Research, Chile: Project PAI-80160043 BAQUIANA, UCM/IRD), MSH (Maison des Sciences de l'Homme SUD, France: Project PANARCHI 2017-2018, IRD/CNRS/UCM/UNJU) and ANR (The French National Research Agency, France: Project ANR-06-PADD-011-EQUECO). We thank Pablo Jara-Valdivia and Marcela Calquín for their contributions to the participatory process with the Lipimávida community, and Mathieu Dionnet, co-organizer of the workshop "Common goods and participatory methods" (MSH-SUD, 16-18/05/2018, Montpellier, France). Thanks are due to all the producers, development agents and local authorities involved with us in these projects.

ABSTRACT

Valorising the biocultural heritage of common goods could enable peasant farmers to achieve socially and economically inclusive sustainability. Increasingly appreciated by consumers, peasant heritage products offer small farmers promising opportunities for economic, social and territorial development. To identify the obstacles and levers of this complex, multi-scale and multi-stakeholder objective, an integrative conceptual framework is needed. We applied the panarchy conceptual framework to two cases of participatory research with small quinoa producers: a local fair in Chile and quinoa export production in Bolivia. In both cases, the "commoning" process was crucial both to bring stakeholders together inside their communities and to gain recognition for their productions outside and thus reach social and economic inclusion. Despite the difference in scale, the local fair and the export market shared a similar marketing strategy based on short value chains promoting quality products with high identity value. In these dynamics of biocultural heritage valorisation, the panarchical approach revealed the central place as well as the vulnerability of the community territory. As a place of both anchoring and opening, the community territory is the privileged space where autonomous and consensual control over the governance of common biocultural resources can be exercised.

Keywords: adaptive cycle; inclusive agriculture; participatory action research; short value chain; territorial development

1. Introduction

Activating the biocultural heritage of peasant—or family—agriculture has been proposed to promote the social and economic inclusion of the peasant sector in a perspective of sustainable and inclusive agriculture (Walshe and Argumedo 2016; Swyderska et al. 2018). For millennia, peasant agriculture has satisfied the food needs of the majority of the humanity, modeled rural landscapes and maintained agrobiodiversity. It thus represents a form of biocultural heritage that encompasses a range of natural and cultural objects—from genes to landscapes, from knowledges to practices—all rooted in the history and ecology of local societies (Gavin et al. 2015).

Yet, despite its recent recognition by international organizations—FAO declared 2014 "International Year of Family Farming"—and by consumers who express a growing demand for quality products with a local identity, peasant agriculture remains marginal in public policies. In a majority of countries, these policies continue to promote the fragmentation of family farms in favour of the agro-industrial sector, whose environmental, social, ethical and aesthetic costs are however increasingly criticized as they become more widespread (e.g. epizootic outbreaks, soil degradation, biodiversity loss, farmers' indebtedness, livestock cruelty, destruction of amenities) (Ioris 2016).

In response, a number of alternatives seek to promote the specificities of peasant agriculture around the values of territorial identity and biocultural heritage. Because of their socio-cultural and local roots, the objects of the peasant heritage (e.g. landraces, vernacular architecture or gastronomy) are distinctive of the territory. As such, they become vectors of social and territorial identity for those who produce them and, being increasingly valued by consumers, they also become opportunities for the economic inclusion of peasant farmers, for example in fair-trade or short supply chains.

Territorial identity, as a form of collective symbolic capital, may be activated through distinguishing signs linked to a place, know-how, or product, which reinforce social identity and inclusion and also contribute to the protection of common natural resources (Macías Vázquez and Alonso González 2015). The promotion of symbolic capital can therefore increase the economic value of material productions from agriculture, food processing or handicrafts. But this process of creation/accumulation of symbolic capital runs the risk of being appropriated by exogenous actors like finders-keepers, mandated by private interests to capture the value generated by local communities (Macías Vázquez and Alonso González 2015). When they are emblematic of a territory, biocultural heritage objects have an obvious dimension of common goods, even in the case of private properties like buildings (e.g. Andalusians windmills, Gascony dovecotes...) or privately-owned animals of local breeds (e.g. Scottish Highland cattle, Chilean Araucana chickens...). The conception of biocultural objects as—at least partially—common goods is also supported by their transgenerational value as they are both an inheritance from the past (even recent) and a legacy for the future, and not just the property of their current owners only.

Another way to value peasant biocultural heritage is through fair-trade and short value chains, directly reconnecting producers and consumers (Contreras et al. 2014). Short value chains are not necessarily local: they may be short because of the small number of intermediaries, not because of geographical distance. In fact, in several cases, peasant producers see the export market as more stable and fair than the domestic market (Soper 2016). The concept of nested markets describes arrangements that allow small local producers to access increasingly globalized markets without losing control over the production process and local/global connections (Grivins and Tisenkopfs 2018). Consumer awareness of these local/global connections and their solidarity with producers are key factors for the socio-economic inclusion of small farmers (Castaldo et al. 2009). Successful initiatives of community-supported agriculture around the world show that this alternative model is also economically viable (Blay-Palmer et al. 2016).

The announced benefits of inclusive development point to greater prosperity and economic equity for more people and territories (Chakrabarti 2014). But inclusion requires not only attention to the excluded: it also needs an explicit transformational strategy to align current economic and political trajectories with long-term ecological and social realities (Beling et al. 2018, De Schutter 2011). Two major obstacles arise there: the dominant discourse on the virtues of globalized commercialization and the apolitical tradition of many social organizations (Isgren and Ness 2017). To overcome them, some suggest replacing the narrow concepts of development and growth with those of inclusive sustainability (Essex and Read 2016) and good living (Beling et al. 2018), which prioritize economic localisation and cooperation among social actors in an integrating and ethical vision of their ecological and social responsibilities. Beyond economic growth, peer cooperation creates a protective space to jointly tackle socio-economic and environmental uncertainties. Cooperation generates common knowledge through shared learning of practical skills in management, marketing or communication and, at the same time, strengthens the autonomy of local actors vis-à-vis uncontrolled outsiders (Lucas et al. 2016).

In practice, the participatory valorisation of a biocultural heritage includes: context analysis, rescue of the heritage object to be promoted, and shared design, all of which are interrelated. In shared design, the promoters of the initiative, often technical institutions, NGOs or universities, can suggest objectives and methods that local actors reinterpret and appropriate in the participatory processes. To access the market, some consider it necessary to improve the quantity and quality of the product in order to achieve a high and homogeneous standard, a process that would imperatively require the support of technological institutions (FIA 2015). However, support institutions must guard against the temptation of "command-and-control" that can undermine the empowerment of local actors (Cox 2016).

Quinoa provides exemplary cases that facilitate a more complete analysis of the question of peasant inclusion through the valorisation of biocultural heritage. This ancestral grain from the Andes and the Chilean coast is emblematic of the rescue and valorisation of the agricultural heritage in Bolivia since the 1970s (Barrientos et al. 2017; Winkel et al. 2014, 2015) and more recently in Chile and Peru (Bedoya-Perales et al. 2018; Delatorre-Herrera et al. 2013; Lacoste et al. 2017; Núñez and Bazile 2009, 2010). Quinoa is promoted in the media

as a superfood, both healthy (high in protein, gluten-free) and authentic (under the questionable slogan of "rice of the Incas"). Its production by small, largely organic farmers, has further enhances quinoa's popularity. While the rise of quinoa has allowed many peasant producers access to the global market and to thus achieve socioeconomic inclusion, it also poses real or potential environmental, social, and economic risks, which could lead to the exclusion of small producers and benefit economic agents better prepared to face these risks. Multiple actors with different motivations and priorities (governments, networks and transnational corporations, etc.) question the relative control of quinoa production and commercialization by small producers and their organisations (Zandstra 2015).

The growing complexity of quinoa's value chain has led to reflections on inclusive models for peasant producers that can generate social, environmental, and economic benefits for all in the value chain. Two recent studies focusing on Bolivia and Peru—the world's leading exporters of quinoa—point to the association of producers and collaborations between producers, processors, traders, and consumers as levers in an inclusive model (Böhm 2016; Zandstra 2015).

Unlike highland Andean countries like Bolivia, whose production has dominated the world market for decades and remained in the hands of small farmers' organizations with only late governmental support (Laguna 2011; Zandstra 2015), in Chile the recent expansion of quinoa has been driven by state institutions for technical assistance, training, and credit, who involve small producer and a dynamic agribusiness sector (PUC 2017). Despite their socioeconomic specificities, in both countries the structure of the economy is based on the exploitation of natural resources for export, and peasant family agriculture remains marginal in terms of GDP with structural poverty and social exclusion (Salcedo and Guzmán 2014).

2. Theoretical and methodological framework

This study is based on the concepts of biocultural heritage, commons, and inclusive economy and uses the methodology of participative-action research in the field and panarchy for the integrative analysis of complex socio-ecological transformations.

Biocultural heritage, commons and inclusive economy

By definition, biocultural heritage is both a vector of identity—a heritage of a common local past—and of sustainability, considered of sufficient socio-economic, cultural, or environmental importance to be transmitted to future generations. Our working assumption is that biocultural heritage can contribute to the economic and socio-cultural inclusion of peasant farmers, locally (in tourism, free fairs...) and non-locally (e.g. export market). These complementary dimensions of identity and sustainability, the local and non-local, place biocultural heritage at the centre of territorial dynamics aimed at social inclusion and the preservation of common welfare.

Commons are still often considered as simple resources, either tangible (water, land, seeds, etc.) or intangible (with intellectual property interests). In this view, commons differ from private or public goods because they are objects of rivalry but without exclusivity, at least

176 within a community. However, considering that this definition obviates the social and
dynamic dimensions of common goods, some authors emphasize that no common goods exist
178 without community (Ostrom 1990); a common good is not only a resource, but also the set of
rules and values mobilized by the community that care for that resource (Bollier 2015;
180 Gibson-Graham et al. 2013). For this reason, Bollier (2015) proposes replacing the word
"common" with the verb "commoning" to highlight all the actions of mutual aid, negotiation,
182 communication, and experimentation mobilized for the dynamic management of shared
resources. "Commoning" encompasses production, governance, culture, and personal interests
184 in an integral process. This alternative approach is enacted by responsible local communities
that define their own objectives and rules in relation to their resources (Bollier 2015).

186 Aimed at meeting basic needs and rights (food, health, education, etc.), common goods
naturally focus on the social inclusion of individuals and families marginalized by the market
188 (Bollier 2015). The second assumption of this study is that socio-cultural inclusion contributes
to economic inclusion because, by cooperating and activating symbolic and social capital,
190 small producers generate volume and commercial capacity (FIA 2015). The cooperation of
peasant producers appears key to building a redistributive model that improves their economic
192 income.

Resilience theory, adaptive loops and panarchy

194 Resilience theory explores how the social, economic and environmental components of a
socio-ecological system interact across time and space to determine its capacity for change
196 (Walker and Salt 2006). The adaptive loop¹ model summarizes the possible transformational
paths of a socio-ecological system or subsystem into four phases of growth (r), conservation
198 (K), release (Ω) and reorganization (α), the latter permitting the emergence of a new system
(Holling 1973).

200 The position of the considered system in the four possible phases depends on the degree of
organization (connectedness) and the amount of resources (potential) accumulated in the
202 system. Connectedness and potential are defined by the ecological, economic or socio-cultural
specificities of the system identified after an integrated assessment of its situation and
204 dynamics.

Adaptive loops are not 4-phase sequences repeating themselves in a deterministic way.
206 Depending on adaptability, shortcuts can be opened between different phases that allow a new
system to emerge without going through the destructive release phase (Ω). In an adaptive
208 system, these shortcuts are the innovative paths to sustainability. Innovation also occurs at the
end of the reorganization phase (α), when weak internal control (low connectivity) allows
210 external opportunities ("chance events") to take root and open a path for unanticipated growth
(r) for a renewed system.

¹ We use the term "adaptive loop" to avoid the connotation of deterministic recurrence of the term
"cycle", originally coined by Holling (1973).

A panarchy represents a hierarchy of several adaptive loops, nested in increasing levels of organization (or scales), that interact with each other and drive the dynamics of the entire system (Gunderson and Holling 2002). Typically, a panarchy in a socio-ecological system is made up of nested loops of households—the basic units of living and decision-making—, themselves anchored in the territory and its economic activities and, further afield, in the entire society that determines socio-demographic rules and conditions.

In a panarchy, different types of cross-scale interactions can be recognized, including: the "revolt" connection—when the collapse (Ω phase) of a small-scale subsystem propagates into the surrounding system in late K phase—and the "memory" connection—through which a collapsed subsystem reorganizes itself (α) from the resources of the surrounding, higher level, subsystem (Gunderson and Holling 2002).

Adaptive loops and resilience theory have been used to frame the dynamics of change in agricultural socio-ecosystems at the individual farm, territorial or industry level (e.g. Allison and Hobbs 2004; Sinclair et al. 2014; Darnhofer et al. 2016; Slight et al. 2016), but applications of a complete panarchy nesting multiple adaptive cycles across scales remain rare (but see: Soane et al. 2012; Tittone 2014).

General objective of the study

Building on previous vulnerability assessments of two participatory research projects in Chile (Baquiana project) and Bolivia (Equeco project), we used the integrative framework of panarchy to identify the organisational levels, stakeholders and institutions involved in promoting local biocultural heritage for the socio-economic inclusion of peasant communities. Based on this systemic vision of the transformations underway in two socio-ecosystems with different trajectories and purposes, we looked for the cross-scale interactions that underlie them and the rationales implemented by local actors, with the aim of drawing general lessons on the conditions for inclusive sustainability based on common goods.

3. Case 1: Lipimávida, Chile

Socio-ecological assessment

Lipimávida is a locality on the Pacific coast of the Vichuquén commune (*municipalidad*) in the Region of Maule, in central Chile. In 2010, according to the policy for isolated localities (Gobierno Regional del Maule 2012), Vichuquén was considered the most isolated commune in the region in a critical condition with respect to access to services, education, and capacity for consumption. The earthquake and subsequent tsunami of February 2010 devastated Lipimávida. Subsequently, this exiguous coastal area—inhabited although not constructible according to civil security norms—saw the construction of a new village on higher terrain in the locality, while buildings and chalets continued to be built in unauthorized coastal areas.

The locality is a seaside resort comprised of long beaches and a settlement of residents historically dedicated to family agriculture and the production of woven and ceramic handicrafts made by traditional local techniques. Its location at the end of the J60 coastal

route gives Lipimávida a singularity and isolation, making it attractive for tourists looking for quiet seascapes and a pleasant Mediterranean climate.

Among the gastronomic attractions of the locality is the papaya, whose "trees" are part of the local landscape in patios and orchards. The women prepare preserves, jams and desserts that, together with the seafood and peasant cuisine, characterize the Lipimávida table. Another crop that stands out in the memory of the residents is quinoa, whose local ecotype differs from the Andean highland ecotypes. Specific to the Pacific littoral, it was domesticated by ancestral populations of the central and southern coastal areas of Chile. In Lipimávida, older people remember that quinoa's annual harvest ensured food for winter (Cubillos-Celis et al. 2018). They can still describe the practices of sowing, harvesting, and post-harvesting, in particular the sorting, cleaning and desaponification of the grains. As in other regions, the time and effort required for these tedious post-harvest processes usually carried out by women are the main reasons for the decrease in the amount of quinoa in the local diet. Therefore, although quinoa has been part of local history and food, today few produce it and few consume it. Still, with the media attention recently given to quinoa as a superfood, inhabitants of these rural coasts are beginning to recover it as part of their traditions, seeing an opportunity to improve and diversify their family incomes.

At the scale of the Maule region, massive forest monocultures, misuse, pollution, and diminution of water and arable land resources, degradation of rural and urban landscapes, drought and wildfires are associated with an economic and social model that destroys the local natural and cultural heritage. In 2017, the region experienced the worst wildfires in the last 40 years (CONAF 2017). However, several initiatives reflect a growing awareness of socio-environmental issues, illustrated in the architectural restoration of the heritage village of Vichuquén after the 2010 earthquake and the local agreement on watershed management implemented since 2017 by the National Agency for Sustainability and Climate Change.

In Lipimávida, despite an institutional and political context promoting individualism through elective democracy, generalized private land property, and a neoliberal economy, the vitality and cultural identity of local associations maintains a high degree of social cohesion among members. Also noteworthy in this isolated community, some people have significant experience of exchange with foreign countries, in the marketing of papaya to Belgium or the sale of handicrafts in several European countries. These successful experiences in marketing high quality food and handicrafts proved valuable for the launch of a pilot project on local biocultural heritage.

The Baquiana Project implementation

In June 2017, the Baquiana research team initiated a collaboration and exchange of knowledge and experience with a focus group of a dozen residents (11 women, 1 man), all small farmers or artisans. Then, 13 meetings with an average attendance of 10 people, and 14 individual interviews were realised during the 2017-2018 period. From the beginning of this participatory process, the researchers sought to articulate the interests, positions and wishes of the focus group with regional and local state and market actors. This was possible thanks to the support of the Vichuquén commune, where both the Mayor and professionals of

PRODESAL (Local Development Program) demonstrated flexibility in their annual programs to host this initiative, providing time, tools and socio-technical knowledge.

Focusing on the production of quinoa, the preliminary assessment study established the patrimonial character of this product in the area and its potential for the economic inclusion of peasant families (Cubillos-Celis et al. 2018). A complementary study examined the social dynamics within the group of peasant actors involved in the co-construction of the pilot project associated to the participatory research (Miño-Baes and Viedma-Araya 2019).

In the course of the participatory concertation, the initial focus on quinoa suggested by researchers was challenged and reoriented towards the valorisation of the local tradition of a mix of food and artisanal products of biocultural resources. In addition, local actors expressed that, although most did not cultivate quinoa, their problem was not the "rescue" of the crop, which could be bought from other communities and particularly from the neighbouring region of O'Higgins (Lacoste et al. 2017; Núñez and Bazile 2009). Rather, in a meeting with an expert in threshing and de-saponification of quinoa, they became convinced that cleaning the grain is a complex process and that it was better to buy quinoa from other producers. Similarly, after a participatory workshop with an expert in the co-design of agricultural development projects, they felt that for them, the innovation of producing quinoa as a vegetable (Sáez-Tonacca et al. 2018) was still premature and risky. Instead, they saw a promising opportunity in the same expert's proposal to activate local production and human capacities through short value chains. The pilot project "Lipimávida Heritage Fair" was then co-constructed by researchers and locals with the aim of promoting the local biocultural heritage by combining agricultural and craft products in a unique commercial offering that showcased the knowledge and skills of the inhabitants of Lipimávida.

After opening in January 2018, the heritage fair has been operating regularly, not just in the summer season but also on all dates when tourists are received. Members of the group are engaged in a business that matches their interests and possibilities, offering fresh and innovative products that are affordable to the diverse public visiting them.

4. Case 2: Salar de Uyuni, Bolivia

Socio-ecological assessment

The observations and data that follow describe the situation in the region with the highest commercial production of quinoa in the world between 2007 and 2010, as analysed in the framework of the Equeco project. Winkel et al. (2016) present a detailed analysis of this case, however here we only address salient points that add new reflections on the issues of biocultural heritage and collective action.

The study area is located in the southern highlands of Bolivia, on the banks of the Salar de Uyuni, where plains at 3,600 meters above sea level alternate with volcanic reliefs that reach to more than 6,000 meters above sea level. This extreme environment of high desert has been occupied for millennia by agropastoralists that raise camelids and cultivate quinoa and potato (Cruz et al. 2017).

330 Despite its extreme geographic conditions, this high altitude desert was traditionally
connected to the Andean "archipelago" (Murra 1984). For millennia, commercial caravans
332 allowed local populations to manage resources of diverse ecosystems, exchanging goods such
as salt, minerals, quinoa, wool and meat from the Salar highlands for corn, coca, cloth, etc.
334 from the Andean valleys and the Pacific coast. Over time, this ancestral subsistence strategy
has been complemented by temporary migration for work in mining, agriculture and various
336 activities in more or less remote cities.

Land tenure, characterized by the common use for grassland and family usufruct for cropland
338 (Vassas-Toral 2015), confers a certain social equity in the access to land while protecting the
communities—through the absence of a land market—from the risk of excessive
340 concentration of land or outsiders' land-grabbing (Winkel et al. 2016). Common pastures are
generally located on plains, while family croplands were traditionally located on slopes, a
342 disposition reflecting ancestral ecological knowledge regarding the distribution of frost risks
in mountain areas² (Pouteau et al. 2011). In this desert area, each quinoa harvest results from
344 a biennial dry fallow cycle and thus represents a doubled land area: the current cultivated
field, plus the ploughed fallow waiting for the next year's crop. These specificities of
346 community land tenure and biennial dry fallowing, which protect communities from land-
grabbing and allow commercial production without irrigation, are central to understanding the
348 sustainability of rainfed production in the region.

In the early 1970's, after massive job cuts in the mining and public sectors due to structural
350 adjustment plans, smallholder families from indigenous communities of the Salar of Uyuni
initiated the expansion of quinoa as a cash crop in response to increasing demand for quinoa
352 in neighbouring Peru, a traditional importer of *Quinoa Real*—the local quinoa ecotype of the
Salar region. This initial phase of commercial production was favoured by a donation of
354 tractors from a Belgian NGO (Laguna 2011) and by Peru's policy of supporting Andean food
(Kerssen 2015); a case of "chance events" as coined by Gunderson and Holling (2002). This
356 expansion of commercial quinoa production sparked a strong territorial dynamic that
included: the partial mechanization of quinoa crops, which required converting much of the
358 flat grasslands—the only spaces accessible to tractors—into croplands; and the replacement of
the distant and prolonged emigration with various forms of seasonal mobility towards nearby
360 urban centres that became the principal place of residence of many quinoa producers.

In the observation period, the study area was populated by approximately 12,000 families of
362 quinoa producers, most of them of Aymara or Quechua origin with a strong cultural identity
(Vassas-Toral 2015; Vieira-Pak 2015). This factor of social cohesion is also observed in the
364 rotating positions of responsibility for common interests that are assumed by members of the
community. For each producer, complying with these community obligations and paying land
366 taxes guarantees the right to access the usufruct of the land, even if his residence in the
community is intermittent (Vassas-Toral 2015).

² Due to its higher density, cold air drains to the lowlands at night thus increasing the risk of frost there while slopes remain less exposed.

In relation to this lively tradition of self-management and participation in collective life, local populations have demonstrated their organizational and negotiating capacity when they formed, with the encouragement of European NGOs, powerful associations of family producers. Organizations like CECAOT (Central de Cooperativas Agropecuarias Operación Tierra, founded in 1974) and ANAPQUI (Asociación Nacional de Productores de Quinoa, founded in 1983) encourage the production, transformation and marketing of quinoa, including export to new niche markets with organic and fair-trade certifications (Laguna 2011; Tschopp et al. 2018).

As a corollary of their success in the commercial production of quinoa, local producers have promoted a rebalancing of regional territorial development, investing their new income not so much in rural communities but rather in nearby cities (Salinas de Garcí Mendoza, Llica, Uyuni, Challapata, Oruro, etc.). Compared to the rural sector, the provision of health services, education, electricity and water, transport, and connection in the urban sector allows for improved training and the professionalization of their children (Vassas-Toral 2015). Taking advantage of their dual residence between rural and urban areas, most families combine two or more activities in agriculture and livestock, handicraft, transport, commerce, mining, urban employment, tourism, etc. (Vassas-Toral 2015). Among their agricultural activities, families conserve a self-consumption production of quinoa and potato, while the breeding of camelids and sheep—unprofitable and poorly compatible with urban residency—has diminished. Handicraft (wool) and tourism (accommodation, driver-guide) remain marginal. Non-agricultural income offers a guarantee against the volatility of quinoa prices, which peaked in January 2014 (approx. 6,000 USD/ton) and then stabilized at around 1,200-1,600 USD/ton.

While the assessment of peasant family income remains uncertain, a survey of 36 households in the study area in 2007 (when quinoa was paid to the producer at about 750 USD/ton) reveals the great disparity present within a single community, with incomes ranging from 200 to 18,000 USD per year (Winkel et al. 2016). This disparity in family income reflects differences in social status (e.g. young single mothers vs. extended families) and inequalities in economic power, both of which influence access to land since the inheritance of land use right in the region is generally patrilineal and the extent of cultivated land depends on the ability of each producer to assume the cost of hiring a tractor driver to plough and sow the land.

With regard to the regulation of access to land, customary rules controlled by communities and indigenous authorities mix with national laws adopted by the central government. More specifically, agricultural production is governed by local consensual and collective norms, which compete with food certification controls and foreign trade regulations. Low acceptance rates and the lack of practical implementation result in most of these rules not being applied consistently across the region.

The Equeco Project implementation

The Equeco project was launched in 2007, more than three decades after the start of quinoa export production in the Salar de Uyuni region, a process that can be dated from the arrival of the first agricultural tractors in late 1969 (Laguna 2011). Questioning the sustainability of a

process that has been going on for more than 30 years, project researchers examined the social and environmental history of local quinoa production (see Winkel et al. 2014, 2015, 2016, for more details). Focus groups were comprised of quinoa producers from various rural communities around the Salar de Uyuni as well as the NGO AVSF ("Agronomists and Veterinarians without Frontiers"), involved in a regional project for the sustainable management of local agro-pastoral systems.

The participatory methodology of the project was based first on participant observation, where researchers immerse themselves in the daily life of local producers during many months. Based on this initial assessment of the local situation, role-playing workshops followed by group analysis sessions were held in the communities to discuss with participating producers what happened during the game and to analyse the similarity between game and reality (Vieira-Pak 2015). As regards local development, researchers issued recommendations for local stakeholders (producers, authorities, NGOs...) particularly concerning the consensual renewal of communal norms of land access and use. On an international scale, researchers accompanied the renegotiation process between producer organizations and FairTrade International on the new fair-trade certification standards for quinoa (Salliou 2011).

5. Adaptive loops and panarchy

Case 1: Lipimávida (Chile)

Returning to the case of Lipimávida, three levels of analysis of the ongoing innovation process emerged from the study: the group of food and handicraft producers, the tourism activity in the locality of Lipimávida, and the socioeconomic context of the Vichuquén commune.

First loop: quinoa and handicraft producers

The concertation process among the local participants in the Project resulted in the decision to establish a new fair of heritage products in the community, with the objective of allowing its participants to market their handicraft, food, and local products in their own territory and without intermediaries. In its organizational phase, the fair group began with 12 members, maintaining oral agreements for its regulation, sustained by the bonds of trust that existed among the participants. This group of a few people did not need a large organization or a long dialogue to start operating. To ensure a sufficient number of potential clients, the group decided to hold the fair on Sundays during the summer season (January, February). Once the offer of products, the type of activity, and its frequency were agreed upon, the members of the fair, with the help of the Project facilitators, were able to mobilize external support from the commune, rural development services (PRODESAL) and from the parish. Through this, they obtained the official authorization to occupy public space, publicity for the inauguration of the fair, and the use of a car park for their clients.

This brief analysis (see Cubillos-Celis et al. 2018, and Miño-Baes and Viedma-Araya, 2019, for a complete description of the process) highlights that the local producer group is in an

448 initial phase, organized around a project of local fair with a well-defined orientation:
promoting craft and food products from their biocultural heritage. Yet, this producer group
450 has chosen to maintain a diversified offer and, up to now, its few members have decided to
govern themselves by simple oral agreements. There is no evidence of extreme product
452 specialization, high investment in economic or work resources, organizational complexity or
connectivity that could hinder the adaptability of the group and compromise the viability of
454 the heritage fair project. For all these reasons, the current phase can be referred to as an initial
(*r*) growth phase.

456 *Second loop: local tourism*

Since the beginning of the 2000's, the tourism sector in Lipimávida has grown consistently.
458 The number of tourist establishments increased from 6 in 2004 to 70 in 2018, with a
combined accommodation capacity of more than 400 people. In this locality with only one
460 hotel, this development is mainly due to the decision of local residents to convert part of their
agricultural land for the building of chalets rented to tourists on weekends or for longer
462 holidays.

The locality has 6 restaurants that offer a variety of menus with fish, seafood, quinoa, and
464 papayas. Several stores sell fresh and processed food products, where quinoa and papaya
stand out. The direct sale of fresh vegetables, medicinal plants, eggs and honey, as well as
466 local handicrafts, is also important in the residents' homes. In fact, handicrafts are an essential
component of the local tourism market, with exceptional production in clay (*greda blanca*)
468 and sheep's wool, spun locally and coloured with natural dyes then transformed into highly
valued fabrics, with some sold in European markets.

470 Despite the high potential for tourism in Lipimávida, the sector shows signs of vulnerability.
The town is located on a dead-end road, connected to other coastal cities by a single route (J-
472 60) that is rapidly saturated in the peak season. This causes numerous traffic jams repeatedly
reported by the local press. In addition, in the Maule region in general and in the town of
474 Lipimávida in particular, water scarcity seriously affects the supply of drinking water and
sewage services. The seasonal influx of tourists into the region exacerbates this problem.
476 Tourist constructions directly bordering the ocean coastline seem vulnerable because they
violate building regulations in seismic risk areas.

478 Local tourism in Lipimávida can be characterised as an advanced (*K*) phase of the adaptive
loop since many indicators reveal: the concentration of financial and social resources
480 (*potential* axis) in tourism-related activities (accommodation, restaurants, shops and crafts);
and strong pressures (*connectedness* axis) on the local road, land, and water resources, which
482 present risks for tourism development and the commercial potential of the territory.

Third loop: communal socio-economic dynamics

484 In administrative and political terms, Lipimávida depends on Vichuquén that supports
different types of projects aimed at contributing to the development of the territory and the
486 well-being of its inhabitants. Crucial for Vichuquén and the surrounding communes, in 2017

the National Climate Change Agency initiated a "Voluntary Agreement" for the management of water resources of the Llico, Vichuquén, Torca, Tilicura, and Agua Dulce watersheds. Through a participative process, a public-private alliance has been formed bringing together 24 organizations with the participation of public administrations, civil society organizations, cultural groups, the scientific academy, the Army and private companies. The projects promoted by the Voluntary Agreement address diverse areas such as environment, agriculture and industry, education, health, tourism and culture, so as to coordinate efforts and resources and integrate different actions that contribute to the sustainable development of the basin in the face of climate change, and the foreseeable decrease in water resources. Although some projects are already underway, others have not yet begun and all options remain open, because the Voluntary Agreement is an evolutionary process in which new initiatives may be presented.

Due to the active coordination (*connectedness*) of multiple projects in different fields, and no sign of exhaustion of social and financial capital (*potential*), the socio-economic sector at the communal level can be considered in a dynamic (*r*) phase of its adaptive loop.

Integrating the adaptive loops in a panarchy

In the end, the integration of the three adaptive loops shows a tourism subsystem in advanced (*K*) phase, prevailing over any other economic activity, and vulnerable not only to occasional seismic hazards but also to the ongoing overexploitation of land, water and infrastructure resources. Yet, the subsystems immediately below and above, both in a (*r*) phase, show a responsible commitment to paths of sustainability (communal loop) and socio-economic diversification and autonomy (producers' loop), all favourable to managing the vulnerability of local tourism activities (Fig. 1, case 1).

Fig. 1. Schematic representation of the panarchies of the two study cases. For each case, three nested subsystems are hierarchically scaled and their respective positions in Holling's adaptive loops are symbolized according to the right-hand insert.

Case 2: Salar de Uyuni (Bolivia)

First loop: quinoa producer families

516 In the 1980's, Bolivian quinoa growers opportunistically responded to increased demand for
gluten-free, protein-rich, organic food in North America and Europe. These new markets,
518 often labelled fair-trade, did not replace the Peruvian market which remained open to
unofficial trade of conventional (non-organic) quinoa (Gandarillas et al. 2015; Laguna 2011;
520 Rojas 2011). Local quinoa producers thus occupy a diversity of niches in the growing quinoa
market, but did not specialize in this unique production. While only a few continue to raise
522 llama and sheep—an activity with low economic profitability, incompatible with temporary
migration—, most maintain a seasonal rural/urban mobility that allows for off-farm activities
524 in neighbouring cities where producer families live almost year-round (especially those with
children in school). This strategy of on-farm/off-farm pluriactivity involving different family
526 members results in much diversified household economies (Laguna 2011; Vassas-Toral 2015;
Ofstehage 2012; Vieira-Pak 2015).

528 Considering the income of quinoa (*potential*) and the connection to market niches
(*connectedness*), the household economy of quinoa producers shows a situation of multiple
530 trajectories between the growth (*r*) and conservation (*K*) phases. Resolutely engaged in
commercial production, local families still maintain flexibility in their activities, thus avoiding
532 complete specialization in a profitable but risky business. This flexibility is reflected in partial
"back loops" when quinoa producers chose to alternate between multiple on- and off-farm
534 activities and multiple market niches, moving opportunistically from one trajectory to another
(Vassas-Toral 2015; Ofstehage 2012).

536 *Second loop: community territory*

The agricultural landscape of the Salar region has been profoundly modified by the change in
538 land use from pasture to crop fields, with almost all of the mechanizable lowlands now
converted to quinoa fields. More than unclear and controversial land degradation (Walsh-
540 Dilley 2013; Winkel et al. 2012), it is the land area converted to quinoa crops that appears as
the most reliable indicator of the local agroecosystem having reached its maximum carrying
542 capacity, with a significant homogenization of the landscape and virtually no more space
available for new crops.

544 The adaptive loop of the community territory thus appears to be trapped in an advanced
conservation phase (*K*) with vast quinoa monocultures resulting in minimal landscape
546 diversity (maximum field connectivity) and maximum available land capital (potential)
already converted into cropland.

548 *Third loop: socioeconomic context*

The socio-economic analysis of the Salar region highlights contradictory characteristics in
550 local population dynamics, with the national census indicating a continuous population loss
whereas recent studies suggest a "re-peasantization" of the region (Kerssen 2015; Vassas-
552 Toral 2015). In fact, commuting between rural and urban areas remains the current livelihood
strategy for the majority of the population, which implies a continuous reorganization of
554 household and economic activities on a monthly (sometimes weekly) time scale.

The strategy of double rural/urban residence has implications for the norms of access to and use of agricultural resources, since compliance with these norms allows double residents to claim land access rights in their community of origin. Yet, here too multiple rules enacted at different levels of organization (community, nation, international organizations, food industry) are accumulating, and continually rearranged and reinterpreted.

Thus, continuous adjustments in population dynamics (social potential) and land resource management (normative connectedness) indicate an adaptive loop of the social system located in a (α) phase of prolonged reorganization, with temporary emigrants crossing returnees, and with multiples—sometimes unimplemented—land management rules.

Integrating the adaptive loops in a panarchy

In total, the scaling of the three adaptive loops shows a territorial subsystem in a vulnerable (K) phase, but without any apparent risk of a "revolt" type connection since the underlying system is in intermediate (r) phase, with quinoa producers' families maintaining a risk-coping strategy of mobility and pluriactivity on-farm and off-farm. At a higher level, the (α) phase characterizing the socio-economic context leaves open the possibility of multiple initiatives to tackle the issue of the vulnerability of the territorial system (Fig. 1, case 2).

6. Discussion and conclusion

Since localities are at the crossroads of daily actions of local stakeholders and planned interventions of external entities, it is not surprising that their territories emerge from the panarchy analysis as the places where the vulnerability of local socio-ecological systems concentrates. A more interesting result is to identify strengths and bottlenecks at adjacent scales to address issues at this crucial organizational level. We have done this by paying particular attention to "commoning" processes valuing the biocultural heritage in the perspective of an inclusive peasant agriculture.

Commoning to get included

The two study cases illustrate how the inclusion of peasant farming through heritage products operates simultaneously in two directions. First, it operates "inwards", with the inclusion of individual peasants and artisans in local organisations that allow them to act for common objectives, i.e. "commoning" in Bollier's terms (2015). It also operates "outwards" with the recognition of peasants and artisans and their productions by a range of external socio-economic actors: authorities, social and territorial development agents, processors and marketers, gastronomic promoters, media and, finally, consumers.

"Inwards", social inclusion resulted from collaborative processes of decision making, production and valorisation of biocultural goods, with the participation of marginalised people, women (case 1) or smallholders (case 2). Cooperation helps social and economic inclusion through the co-construction of new aspirations and identities, such as initiating and

managing short value chains³ for diverse heritage products (case 1) or for an ancestral ecotype of quinoa, *Quinoa Real*, emblematic of a vast territory (case 2). To individuals and families with little economic power, collective action thus offers new social roles that embody cultural values and imply both their responsibility and their rights (Bollier 2015). The two case studies belong to the category of social innovations resulting from bottom-up, multi-stakeholder and inclusive collective processes that emerge from territories to respond to aspirations for change and local social needs (Faure et al. 2018).

"Outwards", more than just commercial spaces, the local fair (case 1) and the international niche markets (case 2) become spaces for producers to meet consumers directly and for the rest of society to recognize their products.

The cooperation and self-organisation of the producers are the pillars of "commoning", which can be satisfied with an informal but effective grouping (case 1) or form powerful national associations (case 2). Cooperation brings autonomy and, usually, involves a form of self-management that goes beyond the simple need to generate commercial value (Lucas et al. 2016). Solidarity and social inclusion, identity and cultural recognition are also key values for the sustainability of community groups (Lacote 2017).

In a broader perspective, both case studies demonstrate the importance of local action for the governance of biocultural resources, thus corroborating the potential for efficiency and resilience of local self-organization compared to centralized governance of natural resources (Ostrom 1990; Tuttonell 2014; Tschopp et al. 2018).

Local experiences of "commoning" can be difficult to replicate as they are often based on informal networks of contacts and cooperation (Macías Vázquez and Alonso González 2015). The relationship of trust gradually built between the actors can be formalized through a contract of the rights and duties of the participants, such as the renewed norms of access and use of land in case 2 (AVSF 2010). But case 1 shows that in a still incipient innovation process the lack of a formal contract does not prevent—and perhaps facilitates—joint and effective action by the group.

Another key point is the mobilization of consumers in support of producers at the other end of the value chain. In the face of attempts to capture cultural value by exogenous actors, it seems essential to maintain local social control (on the part of producers) and non-local control (on the part of consumers) over the material capital of natural resources and products, but also over the collective symbolic capital of knowledge, norms, images, etc. (Macías Vázquez and Alonso González 2015). This objective of social control over heritage products does not mean that the community of producers withdraws into itself: at the other end of the value chain, citizen organizations concerned about the quality of their food, authenticity, social justice and the sustainability of their modes of consumption can effectively support the orientations of local producers (e.g. through militant fair-trade associations or community-supported agriculture). Sustained public participation in the heritage fair in case 1 and the engagement of

³ Remember that "short value chain" does not refer to the geographical distance between producer and consumer, but rather to the reduced number of intermediaries that separate them in the value chain.

fair trade organizations with quinoa producers in case 2 illustrate the common interest and objective agreement between actors at both ends of the value chain.

It has been claimed that without support from state technical agencies, small producers cannot access high-value markets (FIA 2015). However, the two cases presented here demonstrate that innovations based on the commons do not always require the intervention of centralized entities. The greater efficiency of local entities in the management of territorial resources has been emphasized by Ostrom (1990) to justify self-governance over these resources. The possibility for marginalised farmers to integrate the market for their own empowerment and establish alliances different from those recommended by external agents (government, NGOs, etc.) is an option that can be as innovative and a form of resistance to the "command-and-control" system (Cox 2016). However, there may also be abuses of power games or private interests at the local level, which encourages reflection on how to maintain control over individual or local actors in order to preserve the general interest. In case 2, this precaution led to the consensual renewal of communal norms to control the usurpation by a few of common pastures to convert them into crops with private usufruct.

In both cases, and regardless of their degree of formalization, the new social organizations began with the smallest possible unit: grouping of individual producers (case 1) or indigenous village community (case 2). This guaranteed the autonomy and control of local actors over the new norms to which they would be subject (Ostrom 1990).

In economic terms, the two cases we analysed show that the inclusion of family agriculture through artisanal products and heritage foods can operate by the construction of short value chains both local (case 1) and international (case 2). By distributing added value more equitably, short value chains increase the autonomy of producers while favouring agro-ecological transition (Lucas et al. 2016). This is illustrated in case 2 by the intense work of renewing the community norms for the sustainable use of territorial resources, the result of raising stakeholders' awareness of the ecological and social challenges of the changes underway in their territory.

As a marketing strategy, short value chains often correspond to niche markets oriented towards the product (biocultural good of quality with identity) and the consumer (tourist in case 1, eco-responsible consumer in case 2), rather than towards conventional distributors, who cling to criteria of volume and margins rather than quality, social justice, authenticity, or mitigation of environmental damage. In this short value chain strategy, agrotourism offers local producers a particular opportunity to value their biocultural heritage within their own territory (Bazile et al. 2014; Núñez and Bazile 2010).

Key features of a "valuable" biocultural heritage

The two cases presented show that "valuable" heritage goods are products that combine local identity and the general interest, or, in other words, that unite tradition and innovation. The general interest and innovation around quinoa respond to the growing concerns in global society about issues of nutrition and health, economy and environment, globalisation and social justice. Regardless of the size of the target market, in both cases, local actors have been

able to respond to these concerns which, essentially, consist of finding quality products with an identity that convinces consumers that their purchasing act benefits the common biocultural, social or environmental heritage. The identitarian and traditional dimensions of heritage goods are nourished by the affective relationship that local producers—generally inhabitants or natives of rural areas—maintain not only with their territory (Hinds and Sparks 2009) but also with each other through ties of kinship or friendship (Laguna 2011; Vassas-Toral 2015; Vieira-Pak 2015). Whether consciously or not, this affective symbolic value is integrated into the price that the consumer is willing to pay, generating a positive circle between market, social ties, and biocultural heritage. The strategies of local actors to valorise and commercialise their biocultural goods are then oriented according to these values and expectations of society in general.

Territories, between local identity and non-local connections

In a territorial perspective, the inclusion of peasant agriculture is established under two complementary realities: the anchoring of family producers in their lands of origin even if, as in case 2, families maintain a double rural/urban residence; and a flow of resources, people, goods and information from the "outside" to the productive territory, which is then integrated into new exchange networks, making its heritage known and reinforcing its connections to the "outside".

In case 2, the anchoring and permanence of families in communities is conditioned by the tension between their access to better basic services and their active control over the access and use of territorial productive resources. This tension is resolved by replacing emigration, often long and distant, by a new form of urban/rural mobility within the region that allows compliance with communal obligations and access to land (Vassas-Toral 2015). In centralized countries, as in case 1, this communal control of territorial resources poses the challenge of deconcentration of power and resources of state institutions.

For heritage resources to contribute to the inclusion of family farming, the territorial anchoring must also value a local identity—traditional or innovative—that allows for the elaboration of a story or an image to be disseminated abroad (Annes and Bessière 2018). In this story or image, the territory is highlighted as a source of authentic (made by the inhabitants themselves, not by industrial processes), natural (coming from the ocean, the mountains, the desert, all spaces a priori without contamination...), healthy (of high nutritional value, without chemical additives), aesthetic and cultural products. In case 1, these symbolic values motivated from the start the producers who were relying on their successful experiences with high-quality papaya and handicrafts. For quinoa, the heritage value of its local production and use still needs to be established with more evidence. A first step would be through culinary innovation to generate socio-cultural identity and strengthen the territorial anchorage of peasant agriculture. By betting on local gastronomy and tourism, it is possible to promote biocultural heritage products without having to look for distant markets, which is beneficial for the autonomy of emerging groups of small producers (FIA 2015). In case 2, after 40 years of "generic" quinoa production and a growing competition from Peru, the promotion of *Quinoa Real*'s identity is now the basis of a denomination of origin process

(Soraide-Lozano 2011). However, some analysts suggest that this idea may be inappropriate in the current configuration of the export market where differentiating one Bolivian ecotype from another in Peru does not motivate the final consumer—European or North American—interested in the organic, healthy, or even fair trade nature of the product and not its geographical origin (Böhm 2016). Here, the geographical distance between producers and consumers seems to be an obstacle for the latter to appreciate the biocultural heritage of a distant and unknown territory, especially in the case of a food such as quinoa, which is consumed marginally compared to tea and coffee, for example. Solving these bottlenecks requires virtuous networks between conscious and organized citizens, and a socially and ecologically responsible market, i.e. new terms of the social contract to take into account local requirements in globalized scenarios (De Schutter 2011).

Overall, innovations based on biocultural heritage—whether creative in the case of a new heritage fair or essentially adaptive in the case of sustainable export production—have made it possible to change the local reality of small farmers without hindering existing activities, which seems to guarantee their acceptability and social and economic viability in the medium and long term. In particular, their consensual and progressive nature has made it possible to promote inclusive changes that contribute to good living together.
