Metastasis to the brain is a clinical problem in patients with breast cancer¹⁻³. We mined published microarray data^{4,5} to compare primary and metastatic tumor transcriptomes for the discovery of genes associated with brain metastasis in humans with metastatic breast cancer. We found that the leukocyte receptor cluster member 8, encoded by LENG8, was among the genes whose expression was most different in the brain metastases of patients with metastatic breast cancer as compared to primary tumors of the breast. LENG8 mRNA was present at increased quantities in brain metastatic tissues as compared to primary tumors of the breast. Importantly, expression of LENG8 in primary tumors was significantly correlated with patient overall survival. Modulation of LENG8 expression may be relevant to the biology by which tumor cells metastasize from the breast to the brain in humans with metastatic breast cancer.

Keywords: breast cancer, metastasis, brain metastases, central nervous system metastases, the leukocyte receptor cluster member 8, LENG8, systems biology of breast cancer, targeted therapeutics in breast cancer.

One report described a 34% incidence of central nervous system metastases in patients treated with trastuzumab for breast cancer². More recently, the NEfERT-T clinical trial⁶ which compared administration of either neratinib or trastuzumab in conjunction with paclitaxel demonstrated that in a randomized, controlled setting, in breast cancer patients treated with neratinib, not only was the incidence of central nervous system recurrence significantly lower, the time to central nervous system metastasis was significantly delayed as compared to patients administered trastuzumab⁶. The alarmingly high rate of central nervous system metastasis described, as well as data, both anecdotal² and from a randomized, controlled setting⁶ illustrating that treatment with trastuzumab may be associated with these events demands an enhanced understanding of the transcriptional makeup of brain metastatic tissues to support identification of therapeutic targets, whether they are treatment related or not. We performed a global comparative analysis of primary and metastatic tumors in patients with brain metastatic breast cancer^{4,5}. We discovered differential and increased expression of the gene encoding the leukocyte receptor cluster member 8, LENG8, in brain metastatic tissues of patients with metastatic breast cancer.

Methods

We used datasets GSE10893⁴ and GSE52604⁵ for this global differential gene expression analysis of brain metastatic breast cancer in conjunction with GEO2R. GSE10893 was generated using Agilent-011521 Human 1A Microarray G4110A technology with $n=11$ primary breast tumors and $n=3$ brain metastases from patients with breast cancer; analysis was performed using platform GPL885. GSE52604 was generated using Agilent-014850 Whole Human Genome Microarray 4x44K G4112F with $n=10$ normal breast tissues and $n=35$ brain metastases from patients with breast cancer; analysis was performed using platform GPL6480. The Benjamini and Hochberg method of p -value adjustment was used for ranking of differential expression but raw p -values were used to assess statistical significance of global differential expression. Log-transformation of data was auto-detected, and the NCBI generated category of platform annotation was used. A statistical test was performed to evaluate whether LENG8 gene expression was significantly different between primary tumors of the breast and brain metastases in humans with breast cancer using a two-tailed t-test. For Kaplan-Meier survival analysis, we used the Kaplan-Meier plotter online tool⁷ for correlation of LENG8 mRNA expression levels with overall survival in $n=626$ breast cancer patients.

Results

We performed global comparative transcriptome analysis of metastatic tumor tissues of patients with metastatic breast cancer using published microarray data^{4,5} to describe the transcriptional landscape of brain metastasis in human breast cancer in an unbiased fashion and for the discovery of novel therapeutic targets.

LENG8 is differentially expressed in the brain metastases of patients with brain metastatic breast cancer.

Through blind, systems-level analysis of published microarray data⁴, we identified the

leukocyte receptor cluster member 8, encoded by LENG8, as a differentially expressed gene in the breast metastatic tissues of humans with breast cancer (Table 1). When sorting each of the genes expressed in brain metastases based on significance of difference as compared to primary tumors of the breast in patients with breast cancer, LENG8 ranked 199 out of 17418 total transcripts (Chart 1), equating to 98.9% differential expression. Differential expression of LENG8 in the brain metastases of patients with metastatic breast cancer was statistically significant (Chart 1; $p=5.31E-04$).

Differential gene expression analyses that utilize primary and metastatic tumor tissues to discover genes associated with metastasis can be challenging due to the relatively heterogeneous cellular composition and constitution of the tumor as compared to normal, untransformed (benign) tissues. Thus, to attempt to validate differential transcriptome-wide differential expression of LENG8 in brain metastases in human metastatic breast cancer, we queried a second microarray dataset⁵, here comparing normal breast tissues rather than primary tumors of the breast to brain metastases. Again, we identified LENG8 as a differentially expressed gene in the brain metastatic tissues of patients with breast cancer (Chart 2). When sorting each of the genes expressed in brain metastases based on significance of difference as compared to normal breast tissues, LENG8 ranked 3717 out of 41093 total transcripts (Chart 2), equating to 91.0% differential expression. Differential expression of LENG8 in the brain metastases of patients with metastatic breast cancer was statistically significant (Chart 2; $p=5.71E-05$). Thus, differential expression of LENG8, transcriptome-wide, in the brain metastases of women with metastatic breast cancer was conserved across two independent microarray datasets, both when compared to benign and transformed breast tissues.

LENG8 is expressed at higher levels in the brain metastases of patients with metastatic breast cancer.

We obtained exact mRNA expression levels for LENG8, in primary tumors of the breast and in brain metastasis of patients with brain metastatic breast cancer to determine direction and statistical significance of change in LENG8 expression in brain metastatic tissues. LENG8 was expressed at higher levels in the brain metastases of patients with breast cancer as compared to primary tumors of the breast, and this difference was statistically significant (Figure 1; $p=0.000663$).

LENG8 expression is significantly correlated with survival outcomes in human breast cancer.

We performed Kaplan-Meier survival analysis⁸ in $n=626$ breast cancer patients in total, to evaluate whether LENG8 tumor expression was correlated with survival outcomes in breast cancer. We observed a statistically significant correlation between primary tumor expression of LENG8 and overall survival (OS) in patients with breast cancer (Figure 2). Patients whose primary tumors expressed low levels of LENG8 possessed median OS of 63.96 months, while patients whose tumors expressed high levels of LENG8 possessed median OS of 106.8 months. This difference in OS based on LENG8 tumor expression in patients with breast cancer was statistically significant (Figure 2, Chart 3; logrank p -value: 0.043; hazard ratio: 0.72 (0.53-0.99)).

1 Thus, by mining published microarray data^{4,5} in an unbiased and systematic fashion, we
2 identified the leukocyte receptor cluster member 8, encoded by LENG8, as among the genes
3 whose expression was most different, transcriptome-wide, in the brain metastases of patients with
4 breast cancer, both when compared to primary tumors of the breast and to normal breast tissues;
5 we observed significantly increased expression of LENG8 in brain metastases as compared to
6 primary tumors of the breast. Further, we found a significant correlation between LENG8
expression and patient survival outcomes, as overall survival was significantly greater in patients
whose primary tumors expressed higher levels of LENG8 as compared to patients whose primary
tumors expressed lower levels of LENG8.

7 **Discussion**

8 We provided evidence here that the leukocyte receptor cluster member 8, encoded by
9 LENG8, is among the genes whose expression is most different in the brain metastases of patients
10 with brain metastatic breast cancer, that LENG8 mRNA is present at significantly increased
11 quantities in brain metastatic tissues as compared to primary tumors of the breast, and that
12 primary tumor LENG8 expression is significantly correlated with patient survival outcomes in
13 human breast cancer. Evaluation of the effects of genetic depletion of LENG8 in mouse models
14 of metastatic breast cancer on metastasis to the central nervous system is merited. Modulation of
15 LENG8 expression may be relevant to the processes by which breast cancer cells exit the breast,
16 enter the vasculature and/or lymphatics, reside in the lymph nodes, evade immune clearance,
17 breach the blood-brain barrier and colonize the brain.

Figure 1: LENG8 is expressed at significantly higher levels in the brain metastases of patients with metastatic breast cancer when compared to primary tumors of the breast.

The mRNA expression level of LENG8 in primary tumors of the breast (left) and in brain metastases of women with metastatic breast cancer (right) is graphically depicted; the result of a statistical test evaluating significance of difference in LENG8 expression between primary tumors of the breast and brain metastases, a p -value, is $p=0.000663$.

Figure 2: Significant correlation between LENG8 primary tumor expression and overall survival in patients with breast cancer.

Depicted in this Kaplan-Meier plot is the probability of overall survival for $n=626$ total patients stratified into two groups, based on low or high expression of LENG8 in patient primary tumors. The log rank p -value denoting statistical significance of difference in overall survival when comparing the two groups, as well as hazard ratio for this comparison is listed above. Listed below is the number of patients at risk (number of patients alive) per interval, after stratification based on LENG8 expression; in the first interval, number at risk is number of patients alive; in each subsequent interval, number at risk is the number at risk less those who have expired or are censored.

Low LENG8 expression: 63.96 months
High LENG8 expression: 106.8 months

Chart 3: Median overall survival is inferior in patients with low primary tumor expression of LENG8.

The median OS (overall survival) of patients with low primary tumor expression of LENG8 and high primary tumor expression of LENG8 is listed in this chart, for $n=626$ breast cancer patients.
